these limits. This argues an approximate two year difference between the sexes in the onset of adolescence. For these reasons it was thought best to consider the sexes separately and to allow a two year variation in each. As in the previous studies, the word birthday has been used in place of year or age in order to avoid the conflicting interpretation. Tables 3 and 4 schedule the normal time of unions in this period. Using the wrist and hand of the female to demonstrate, it will be seen that I believe the phalanges and metacarpals should close sometime between the fourteenth and sixteenth birthdays. Union before the earlier age or open epiphyses after the later is to me an indication of hor-

physeal closures will also be delayed, and whether the growth producing hormone is normal or in excess there will be a continued growth of the long bones with subsequent eunuchoid measurements. If, however, both growth and genital hormones are markedly deficient, one sees the true type of hypophyseal infantilism—an individual much smaller than normal with no primary or secondary sex characters and epiphyses still open a number of years after they should be closed. Figure 11 shows the hand of a girl 13 years of age, who menstruated before 11 (probably because of a hypergonadism, as a result of excess genital hormone from the pituitary) compared to the hand of one who has not

Fig. 10.—Carpal center of 6, 8, 10-year children compared with normal.

monal imbalance, deserving further investigation. Figures 7-10 present the accompanying roentgenograms.

As brought out previously, a deficiency or hyperactivity in its incipience may or may not be reflected in the somatic make-up. The roentgenogram often remains the most valuable aid in diagnosis. Very early closures indicate a hyperactivity of the genital hormone of the anterior lobe of the hypophysis with its resultant hypergonadism, early menstruation, behavioristic problems and cessation of growth. If the growth hormone predominates, there is a potential gigantism that is checked only by the epiphyseal closures after the onset of adolescence. If adolescence is delayed either by primary hypogonadism or by hypogonadism resulting from deficient hypophyseal genital hormone, the epi-

menstruated at 17 years 4 months and is suffering from hypogonadism (as a result of deficient genital hormone from the pituitary) and one of 19 years 6 months who has not menstruated (as a result of primary hypogonadism). The last patient is eunuchoid.

It is therefore apparent that the balancing of the internal secretions accounts in a large measure for the skeletal make-up and that the roentgenologist has within his province one of the best means of diagnosing the endocrinopathies in their incipience. It is with the hope that a greater interest in the subject will be stimulated that this paper is presented.

Observations are still in progress that may further modify the standards during the adolescent age.

34 West Micheltorena Street

ABSTRACT OF DISCUSSION

DR ARTHUR ERSKINI Cedar Rapids, Iowa I shall not attempt to discuss the scientific material presented but I would like to say a word about the paper itself This is the kind of a paper I think we should hear more often Dr Shelton stated at the start what the purpose of the paper was and proceeded to make his points and tell his story in clear concise and correct English, in admirable presentation Furthermore Dr Shelton read his paper in a voice that could be heard and understood I would also like to compliment Dr Shelton on his ability to put such a tremendous amount of information into tables I can say for myself and probably for every one who heard the paper that he has done as he intended to do—stimulate interest in this subject

DR L T LE WARD New York Some years ago in attempting to tell age around 18 years in examining recruits for the army, it was thought that there was a guide in this work but the variation that seems to occur in individuals is so great that, unless Dr Shelton feels differently it would be very difficult in supposedly normal individuals to estimate age when the patient or the individual denies that he or she is of the supposed age that the epiphyses would indicate The same question has arisen occasionally in the United States courts in connection with immigration It is necessary for a Chinaman who claims to be the son of a citizen of the United States to prove his claim to the satisfaction of the immigration authorities If the apparent age of the immigrant differs greatly from the claimed age, it is exceedingly difficult for him to prove his claim especially if he has not reached his twenties If the immigration authorities obtain a certificate from a physician in the United States Public Health Service that the immigrant is three or four years younger or older than he claims to be testimony of other physicians to the contrary apparently do not help him There are two cases involving this question now pending in the United States Court for the Southern District of New York in one of which the x-rays were used to show the growth of certain bones Along similar lines I was asked to study the growth of a gorilla, a baby gorilla that has been in captivity now about a year It may be of some interest to Dr Shelton to know that the growth in the epiphyseal development in this gorilla is more than double that of the human subject for the same period Dr Noback of the New York Zoological Society presented the case to me as one in which the gorilla was supposed to be of a certain age, say 6 months when it was captured I roentgenographed it a few months later and one year after that In that one year the epiphyseal development of the carpal bones was equal to the growth of between two and three years in the human subject I do not know whether these observations have been made before but they are rather interesting I am also studying the epiphyseal development of a young female chimpanzee I understand that a chimpanzee was born in Philadelphia a few months ago and it may be possible that, if somebody would study both the gorilla and the chimpanzee he would find that there is a decided difference in the age growth of the epiphyseal lines

DR F K SHELTON, JR, Santa Barbara, Calif I hope that this work will be found of some practical value It is presented merely as a diagnostic method and is subject to the same criticism When used with clinical judgment I feel that it will be helpful in the differential diagnoses of all metabolic disturbances affecting the bony framework

Aschoff Bodies—Most pathologists hold that the Aschoff node is a specific rheumatic lesion Attempts to produce it experimentally in animals have never been entirely successful, although foci in the myocardium bearing some resemblance have been demonstrated by Carey Coombs, Birkhaug Small and others But, as Miller has pointed out, great caution must be exercised to avoid mistaking the normal for the abnormal animals Heart lesions not unlike Aschoff bodies were found not only in animals inoculated with joint fluids and whole blood from cases of acute rheumatism, but also in a number of controls which had received no injection—Poynton F J and Schlesinger Bernard Recent Advances in the Study of Rheumatism, Philadelphia P Blakiston's Son and Co Inc 1931

ILLRPE'S ZOSTER WITH VARICELLA

A CLINICOPATHOLOGIC STUDY *

R R McCORMICK, MD

FINDLOTT, N Y

The subject of interrelationship of diseases is wide in extent and clinical observation is vast in its scope Progress in the study of this interrelationship is being maintained by the observation of immunities created by certain acute diseases to other diseases, equally acute or chronic

The occurrence of four cases of herpes zoster simultaneously, among apparently healthy young adults in contact in the same occupation, evoked some interest Further interest was created in that one of the patients on the twelfth day following the appearance of the herpes zoster, developed a generalized varicella

Fig 1—Distribution of vesicles and papules on front of forearm Papules in hemorrhagic and pustular stages may be seen

like eruption As the cases occurred in midwinter in the midst of a rather severe epidemic of varicella, a clinical relationship between the two diseases was apparent

Literature dealing with the association of herpes zoster and varicella is becoming increasingly voluminous both in the quantity of clinical cases observed and in the experimental work being performed In 1888 von Bokay¹ of Budapest first reported the possibility of a relationship between herpes zoster and varicella He observed a child who developed typical varicella ten days after an eruption of thoracic herpes zoster in another child in the same family There was no evidence of exposure to ordinary varicella Morley²

reports the case of a girl returned home from school suffering from herpes zoster, her brother, who had been playing with her but had not been exposed to any other infectious case, developed typical varicella thirteen days after the return of the sister. A second case he reports of a boy, aged 5, who developed a right lumbar herpes zoster sixteen weeks after the onset of an anterior poliomyelitis. The zoster eruption was followed in five

herpes zoster in the same individual. Varicella in one individual may be followed by herpes zoster in another.

REPORT OF CASE

History—The patient who developed the varicella-like eruption on the twelfth day after the appearance of the herpes zoster was a white man, aged 23, unmarried and engaged as a shipping clerk. He had never been vaccinated, had had typhoid at 7 years of age, was certain he had chickenpox at 8 years, had had chronic eczema of the scalp for the past ten years, and had acute urethritis (gonorrheal) three years before and chancre of the left side of the scrotum one year before. A blood Wassermann reaction three years before was negative. Ten months before the onset of the herpes zoster he developed a tabetic gait, which was gradual in its onset.

Examination—The patellar reflexes were exaggerated. The pupils were equal and active and reacted to light and in accommodation. Romberg's sign was positive. The tabetic gait gradually became more exaggerated until he was admitted to the hospital for treatment. On examination he was found to have a partial motor paralysis, a loss of sense of position and a paresthesia of both lower limbs. The urinary bladder and rectum were not involved. The paresthesia of the skin extended up to about the level of the umbilicus. The temperature was normal, there was a leukocytosis of 12,000. Repeated examinations of the blood and spinal fluid for a Wassermann reaction were reported negative. Spinal fluid examinations showed clear fluid, no increased pressure, a cell count of 2, a very slight trace of sugar, a slight trace of globulin, smear organisms negative, cultures negative for bacterial growths and a colloidal gold curve of 0001321000. Rest of five weeks in the hospital and the administration of sodium iodide resulted in a rapid improvement, which continued to an apparently permanent recovery.

Course—Dec. 30, 1929, the patient developed a herpes zoster involving the area covered by the distribution of the lower left thoracic nerves. Eight days later (Jan. 6, 1930) he was admitted to the hospital with an extensive zoster of the left

Fig. 2.—Distribution of vesicles and papules on back of forearms and hands.

days by a generalized varicellous eruption. Thirteen days later, two cases of varicella occurred in contact patients in the same ward. Herpes zoster with aberrant vesicles (herpes zoster generalisatus) according to Parounagian and Goodman³ occurs in elderly, poorly nourished individuals. J. B. and Bedford Shelmire,⁴ in 1927, recorded the case of a man, aged 52, who was certain he had not had varicella but who developed a varicella-like eruption following a herpes zoster of the fifth nerve distribution. Fourteen days after the appearance of the zoster in the father, a daughter who had not been exposed to chickenpox developed a typical varicella eruption. In 1929 Bourgin⁵ reported that in two children aged 11 months and 4 years, respectively, who lived in an isolated community, typical chickenpox developed (within ten days in one child and two weeks in the other) after the occurrence of symptoms of herpes zoster in the mother. Vaccination against smallpox had been done some time previously. No infectious disease had been noted. According to Bourgin the etiologic relation between the herpes zoster in the mother and the chickenpox in the children is indisputable. Herpes zoster in one member of a household may be followed by varicella in another. Varicella may follow

Fig. 3.—Mouth and nose showing almost complete occlusion of nasal orifice; papule on lips; two mucous patches on hard palate.

side involving a band of skin 4 inches in width. Two days following admission (January 8) groups of vesicles developed on the face and upper part of the chest. These vesicles arose from a slightly erythematous base. During the following forty-eight hours numerous vesicles appeared over the entire body. The face and upper part of the chest were now covered with vesicles, papules and a few pustules. Some were umbilicated and presented a distinct stinging feeling on palpation. With remarkable rapidity successive crops of vesicle and papules

appeared and became pustular hemorrhagic and gangrenous. Papules and pustules were present on the palms of the hands and the soles of the feet. Mucous patches, some of large size, appeared on the lips, pharynx and palate in the nostrils and on the glans penis. Pustular lesions were numerous on the scalp. With the development of the generalized eruption, the area of herpetic involvement increased. This area showed herpes zoster hemorrhagicus and gangrenosus. There was a generalized enlargement of the lymphatic glands those in the left inguinal region being most marked.

Fig 4—Crater of pock under low power lens. extensive inflammatory exudate extending deeply into tissues

On admission to the hospital the temperature was 99 F. With the appearance of the generalized vesicular eruption it rose to 102.5 F. It remained high the day preceding death being 106 F. Bleeding was frequent from patches in the nostrils, palate and pharynx and occasionally from the urethra. From these numerous mucous patches from the many pustular areas of the skin and from the single large gangrenous region of the zoster, toxic absorption was proceeding. Nourishment was administered with increasing difficulty until vomiting, frequent and blood stained ushered in an extreme alkalosis of the blood. Death took place on the tenth day after admission. The primary cause of death was herpes zoster and varicella; the secondary cause was general sepsis.

Necropsy—A partial necropsy was permitted.

The skin of the entire body was pock-marked and an area over the left side of the trunk appeared gangrenous. Microscopic examination of the pock-marked section showed acute exudative inflammation destroying all layers of the skin and extending into the subcutaneous tissue. Scattered pus cells were contained throughout the subcutaneous tissue. The herpetic section showed gangrenous destruction of all layers of the skin extending into the subcutaneous tissue. There was a slight exudate in the subcutaneous tissue but not as extensive as in the pock-marked section.

Several sections from various areas of the brain were studied with the hematoxylin and eosin stain. The arachnoid showed marked congestion, but no evidence of inflammatory changes or other pathologic conditions. In the glia, no pathologic changes were observed. The blood vessels showed no pathologic condition except congestion. Some of the larger motor cells appeared degenerated giving the appearance of slight vacuolar alteration. Only an occasional cell showed this change and it was limited to the Betz cells. There was some satellitosis about some of the cortical cells in the deeper layers.

The posterior ganglions from the eighth to the twelfth left thoracic were very friable and hemorrhagic. The dura both grossly and microscopically appeared congested; the dural investment of the posterior nerve roots showed cell proliferation. The neurilemma was thickened especially in the portions more

remote from the cord and closer to the ganglions. Microscopically the posterior ganglions were degenerated and hemorrhagic. In a cervical section no pathologic changes were noted other than slight congestion. A dorsal section (level of the tenth dorsal) showed marked congestion, especially in the central part of the cord and in the gray matter. In the left posterior horn was a blood vessel showing a small amount of inflammatory exudate in its adventitial sheath. The large anterior horn cells on the same side showed degenerative changes (vacuolar alteration with swelling and central chromatinolysis) but these changes were not seen to any extent in the opposite anterior horn. Some of the tract cells in the gray matter of both sides appeared degenerated. A lumbar section did not show any pathologic change other than slight congestion. Myelin sheath stains showed no evidence of tract degeneration in any segment of the cord.

RISARCH ON HERPES ZOSTER

The etiology of that group of infectious diseases of which one of the features is a vesicular eruption on the skin is at the present much confused. Rivers has indicated a possible relationship between a series of these diseases beginning with sheepox and horsepox and extending through cowpox, smallpox, varioloid, rasmussen, chickenpox and herpes zoster to symptomatic herpes and epidemic encephalitis. In their clinical manifestations, certain of these conditions resemble one another, others have little in common. One feature present in all of them except epidemic encephalitis is a vesicular eruption of the skin. The responsible agent in most of them is an ultramicroscopic or filtrable virus. In most of the conditions, the skin lesions show similar histologic characteristics. In considering a relationship between varicella, herpes zoster and herpes simplex, similar acidophilic intranuclear inclusion bodies are found in the epithelial cells of the skin lesions. Herpes zoster and varicella attack the epiblastic struc-

Fig 5—Gangrene of skin under low power lens. Both epidermis and dermis have sloughed away down to muscle layers, which show some inflammatory reaction.

tures viz., the skin and the central nervous system. McDonald⁸ records a case of epidemic encephalitis that was preceded by herpes zoster and followed by varicella. Most of these viruses confer life-long immunity. In the Christmas Islands, where excellent statistics are maintained, herpes zoster occurs frequently. Vari-

6 Alkalosis of the Blood. Sodium Chloride 114 mg per hundred cubic centimeters carbon dioxide combining power 73.9 per hundred cubic centimeters of blood plasma nonprotein nitrogen blood 57 mg of non protein nitrogen per hundred cubic centimeters of blood.

cells is unknown there. This points to duality of the viruses. Le Fevre⁸ believes that there is only one virus which produces herpes in adults and neurotic children, and varicella in normal children.

Rivers and Eldridge⁹ have shown from the statistics of the Bellevue and Vanderbilt clinics and from the department of health of New York City that varicella most frequently occurs in children under 10 years of age, while zoster as a rule is observed in older persons. The number of cases of varicella exhibits a markedly constant seasonal variation. The variations in the prevalence of herpes zoster are not regular and do not

Fig. 6—Generalized distribution of vesicles and papules on legs and feet. The umbilication here is well marked.

parallel those of varicella. These investigators¹⁰ after a series of serum neutralization experiments conclude that the etiologic agents concerned with these two diseases are in the majority of instances not identical.

It is evident that, in order to establish the etiologic relation of an ultramicroscopic virus with one of these diseases, it is necessary to reproduce in animals or man, lesions resembling the natural infection.

Cole and Kuttner¹¹ at the Rockefeller Institute found that their attempts to inoculate rabbits, guinea-pigs and monkeys with material obtained from nine cases of herpes zoster were unsuccessful. However, they note that despite cases of herpes zoster being extremely rare in their hospital, they had two cases develop within a very short period of time from being in contact with a third in the same ward. This they report as suggesting a transference of infection from one patient to the other two.

In a consideration of the transference of herpes zoster to human beings, studies of Kundratitz¹² seem to show that herpes zoster can be successfully transmitted to very young children. In wishing to test out von Bokay's hypothesis,¹³ based on clinical observation, that the virus of varicella may under certain unknown conditions produce a typical picture of herpes zoster and that the virus from this lesion may in turn cause varicella, he attempted to immunize children against varicella by the inoculation of material from herpes zoster cases. He reports that he has inoculated material from ten typical cases of thoracic herpes zoster and has had positive results with the material from five of these cases. In his experiments he maintained that a patch of clear vesicles on an erythematous base developing from nine to twelve days after inoculation was considered as a 'take'. Children who reacted positively

were subsequently shown to be immune from varicella. Positive reactions were obtained only in children under 5 years of age. Children who had previously had chickenpox were immune to the inoculation of zoster material, while those who recovered from the inoculation with zoster material were later found to be immune to chickenpox. Several cases of varicella could be traced to contact with children who had developed localized positive reactions from inoculation with zoster material. Kling¹⁴ has reported the successful vaccination of children against chickenpox by inoculation with vesicular fluid. At times a local vesicle or papule would develop at the site of inoculation and occasionally a generalized eruption would appear (true chickenpox?).

In order to establish the interrelationship in this case between the herpes zoster and the generalized vesicular eruption and to observe the possible creation of an immunity, a child aged 19 months was inoculated with fluid from the vesicles. This child had not had any skin lesion since birth and had not been exposed to any case of varicella. No general reaction was noted as one finds in vaccination against smallpox. A very slight reaction took place at the site of inoculation, consisting of the development of a slight erythematous area and formation of a small papule. This papule soon disappeared and the area healed with slight scarification. The erythematous area and the small papule developed between the sixth and ninth days after inoculation. No rise in temperature took place. The inoculated child developed no generalized vesicular eruption.

SUMMARY

Four cases of herpes zoster occurred among persons in contact during an epidemic of varicella. During the course of the herpes zoster in one case a generalized vesicular eruption developed on the twelfth day. This eruption closely resembled varicella. This generalized

Fig. 7—Posterior view of massive herpetic region showing herpes zoster hemorrhagicus and herpes zoster gangrenosus. Umbilicated vesicles and papules in hemorrhagic and gangrenous stage. New crops of vesicles are appearing.

eruption was extensive involving the skin of the entire body and the mucous membranes. Varicella ordinarily a very mild infectious disease occurring during the course of a herpes zoster produced a fatal sepsis due to extensive gangrene of the skin. No cases of varicella developed from contact with this case during the period of the generalized eruption. An infant aged 19 months inoculated with vesicular fluid developed a slight local reaction. This infant has since been exposed to cases

of varicella in children and has not developed any vesicular eruption

The virus or viruses attack the epiblastic structures

Necropsy observation in lesions of the skin showed severe inflammatory and gangrenous involvement of all layers of the skin. The necropsy on the central nervous system revealed extensive pathologic involvement of the posterior root ganglions and the posterior half of the spinal cord—a posterior poliomyelitis.

204 West Main Street

ABSTRACT OF DISCUSSION

DR DANIEL C. O'NEIL, Binghamton, N. Y. Herpes zoster in persons exposed to varicella has been observed by several clinicians and, though considered to be rare is not uncommon. Ormsly, in 1928 reported a case of herpes zoster associated with varicella in a man aged 37, having a generalized varicella accompanied by herpes zoster of the scalp. It was painful and accompanied by swelling of the face and scalp. Chickenpox is an almost universal disease of childhood and confers a life immunity, leaving few individuals that are not protected in adult life, while herpes zoster is more common in the adult and in later life. The case reported is unusual in that this patient had never had varicella until he was 23 years old, although living in a community where chickenpox prevailed and his family thought that he had the disease in childhood. Secondly, he had a chimeroid infection followed by clinical signs of tabes dorsalis three years previous to his fatal illness and these signs cleared up under treatment with iodides. Thirdly, the blood and spinal fluid Wassermann reactions were always reported negative though the tests were made many times. I examined this patient about two years before the onset of the herpes zoster and at that time he gave every indication of tabes dorsalis, the negative blood Wassermann reaction being the only exception. I am anxious to know whether the con-

varicella associations. In one instance the daughter of a man with zoster developed a generalized moderately mild varicella while he was still convalescing from his zoster. In a second instance the 21 months old daughter of a man with nodular zoster developed varicella twenty days after the onset of the father's zoster and in addition there was a history of two children, playmates of this child, having both developed varicella one week before my patient developed his zoster. Just what the exact relationship in connection with this zoster-varicella association is spoken of? Certainly, not that the two are the same diseases acting differently in individuals of peculiar suscep-

Fig. 9—Degeneration of cord as shown by high power lens perivascular infiltration. Left posterior horn of cord showing inflammatory exudate in adventitial sheath of blood vessel, thoracic region.

dition of the cord found at autopsy can explain the tabetic symptoms in this patient two years before death.

DR SIGMUND S. GREENBAUM, Philadelphia. Since Bokay's first report six years ago concerning a possible relationship between zoster and varicella a considerable literature dealing with the subject has accumulated, none of it however, definitely clears the situation since work on the animal transmission of zoster and varicella is contradictory as are cross complement fixation tests with the serums from sufferers of these diseases. Only the apparent clinical association remains on which an opinion can be expressed. I have observed several zoster-

tibility but that they are different diseases, both due however, to organisms related to one another, as are, for example, the different strains of staphylococci or of streptococci. The different clinical pictures that different strains of these organisms may produce are well known. I do not believe however, that the zoster-varicella association is nearly as frequent as a theory of this sort ought to have to support it, their very rarity is rather in support of the theory of coincidence than of relationship. Finally, 90 per cent of the reported cases can be placed here namely, zoster in one followed or preceded by varicella in others of the patient's entourage. I am therefore of the opinion that all real instances of so called zoster-varicella are either coincidences or merely generalized zoster of varying degree.

DR WALTER FREEMAN, Washington, D. C. In a recent case in which a recurrent carcinoma was present the patient developed zoster in the root zone covering the area of the breast, which had been amputated, and with that was associated the eruption of quite a number of vesicles over the body which had the appearance of varicella but which might well agree with the description that Dr Greenbaum has given of herpes zoster generalisatus. The point I wish to bring up, however, is the location of the pathologic changes of herpes zoster, which has been under discussion for a good many years, some individuals reporting the ganglion involved and some the posterior horn of the spinal cord. In the case that I have studied both were involved but it seemed to me that the posterior poliomyelitis was a secondary thing and that the severe necrotic inflammation of the thoracic ganglions was primary. Moreover, in this instance I was able in the ganglion to find certain intracellular bodies that resembled somewhat the Negri bodies or the Rickettsia that occur in certain other virus diseases, and it seemed to point in the direction of an infectious condition rather than a toxic or metabolic one.

DR R. R. McCORMICK, Endicott, N. Y. In answer to the first question asked, whether the pathologic changes of the cord coincided with the appearance of the symptoms of tabes dorsalis some ten months or a year previous, they did not coincide with the pathologic changes in the cord in tabes dorsalis. I appreciate what Dr Freeman said that the pathologic condition in herpes zoster appears first in the posterior ganglions and spreads secondly into the posterior part of the spinal cord.

New Instruments

NICKEL DERMATITIS A NEW SOURCE

FAERETT S LAIN M.D. OKLAHOMA CITY
Professor of Dermatology and Radiology University of Oklahoma
School of Medicine

Metallic dermatitis is occasionally observed in the practice of every dermatologist who attends the laboring people of various occupations, more especially by dermatologists who look after the skin eruptions of employees of large public utility and industrial plants. It has been my observation that the occurrence of a dermatitis occurring on the hands and faces of professional polishers and platers, caused by either the solvent or the salt of a metal, is of more frequent occurrence than the leading textbooks would infer.

Nickel dermatitis has been a subject of rather common discussion in European literature ever since Blaschko,¹ in 1889 first called attention to the susceptibility of workers in industrial plants handling nickel. R. Prosser White² relates several incidents of a nickel dermatitis; also he quotes Rambousek in describing nickel rash as occurring in nickel platers and concludes that the disease is most probably caused by the action of nickel salts. A brief review of American medical literature reveals a lack of information on metallic dermatitis of any kind especially nickel, which is apparently one of the most common of the metallic irritants.

Bulmer and Mackenzie³ who made an exhaustive research of a nickel rash common to workers in the International Nickel Plant of Canada, Limited, have written one of the most elucidat-

Fig 1 (case 3)—Appearance of eruption on temple

ing articles in recent years. Their investigations will doubtless become a guidepost to all medical authors who follow.

During the past year I have observed a new source of dermatitis which may have been observed by others though so far as I have been able to find this is the first report of a dermatitis from such a cause. The past spring and summer I observed two unmistakable cases and possibly a third one of a dermatitis occurring on the temples and ears of men wearing spectacles

2 White K. P. Occupational Affections of the Skin ed. New York Paul B. Hoeber 19 9 pp. 189 191
3 Bulmer F. M. K. and Mackenzie F. A. Studies in the Control and Treatment of Nickel Rash J. Ind. Hyg. 51 5 (Dec.) 1912

with white gold frames. In each case the frames were made of the so called white gold, reported as an alloy of gold, copper and nickel. In the first case the eruption occurred across the bridge of the nose, though in the second and third the bridge of the glasses was of a different material and the eruption occurred on the temples and ears only.

In the first case merely a suspicion was aroused as to the possible etiologic factor, but no further observation was made. The second and third cases were of varying degrees of eruption though marked by a similar appearance, namely, consisting of a margined erythema with medium sized, pruritic papules

Fig 2 (case 3)—Eruption over and behind ear

extending horizontally over the temples and behind the ears corresponding with the temples of the glasses. The papules which were of medium size were deep red, mildly exudative and apparently originating in the hair ducts and orifices of the glands. The eruption in each case occurred after a period of successive warm days during which the patient had perspired freely over his temples.

After seeing a second and then a third case I began an investigation and learned that the frames were made of white gold by a well known optical company. I immediately wrote to the company explaining my observations and received a prompt courteous reply. Extracts from this letter are as follows:

Complaints of the character referred to in your letter of September 23 have reached us at infrequent intervals and a great deal of time and study has been put into this subject by our laboratory.

The trouble seems to be due largely to nickel that is found in white gold alloy. We believe the action is largely electrolytic that is an electrolytic battery action is produced when there are dissimilar metals and an acid or in some instance an all time fluid present and in contact with these dissimilar metal.

When the perspiration which is an electrolyte acts upon the base metal salts are formed and such action is more pronounced in the presence of heat. It is probably a salt of the nickel that causes irritation of the skin where the metal comes in contact. The irritation seems to be analogous to a trouble that is present in the nickel plating industry called commonly nickel itch.

While our conclusions seem to be rather positive in character the remedying of the situation from the standpoint of correcting the inherent trouble has proved very difficult but we have found that by using solid gold in place of gold filled in the electroplating case the difficulty has been overcome. More recently we have developed a plating process passive in its character but

one that has proved very effective in a great number of cases but whether it is the answer in all cases or not we do not know."

Patient 3 T. W. J., aged 47, whose trouble was similar to that of patients 1 and 2 came to the I am Roland Clinic Sept. 23, 1930 complaining of the dermatitis described extending over the temples horizontally and backward behind the ears corresponding exactly with the temples of the frames as illustrated.

He had been fitted by an ophthalmologist the previous January with spectacles of standard white gold frames. No trouble developed until the latter part of August following a succession of warm days during which time he had been perspiring freely. His attention was attracted by an itching, stinging sensation over the temples and ears which caused him to scratch. A few days later he discovered an eruption which gradually became worse. He consulted a dermatologist in another city who applied mercuriochrome 220 soluble suggesting the possibility of a minor infection.

The eruption continued to grow better and worse until he came to our office two weeks later seeking relief. At that time the eruption was so definitely outlined across the temples and behind the ears that no mistake could be made as to its etiology. After the temples of his glasses were changed to solid gold and he was given the application of cooling astringent lotions for a few days the eruption promptly subsided and has not recurred.

There were no metallic stuns on the skin but close inspection of the frames revealed minute specks of corrosion. I conclude that the eruption was most probably due to the sensitivity of his skin to the metal salt.

CONCLUSION

1. Nickel dermatitis is probably more common outside of nickel plating works and the professional laboratories than text books and medical literature would lead one to infer.

2. Three cases due to new white gold spectacle frames were observed within the same season.

3. In modern times when so much jewelry and so many spectacle frames are made of white gold an alloy containing nickel it is necessary to consider this possible etiology in eruptions occurring on areas of the body in contact with such metals.

A CASE OF URTICARIA AND TOXIC ERYTHEMA FOLLOWING THE ADMINISTRATION OF MONO-iodo CINCHOPHEN

THOMAS H. MILLER, M.D., DETROIT

The case of urticaria and toxic erythema reported here is of especial interest in relation to the numerous cases of atrophy of the liver following the use of cinchophen preparations which have appeared in the literature. As recently reviewed by Rabinowitz,¹ the chief symptoms in all cases were constitutional and cutaneous manifestations with the exception of jaundice were apparently infrequent and relatively unimportant. In enumerating the earliest signs of toxicity, pruritus and urticaria are mentioned. Jaundice was not present in this case and the chief symptom which caused the patient to seek relief, was extreme pruritus due to a generalized urticaria.

REPORT OF CASE

Mrs. M. W., aged 54, seen, Oct. 4, 1930, complained of a generalized pruritus of one day's duration, which was particularly marked on the palms and soles. Her general health had always been good except for frequent severe colds during the winter. There was no history of urticaria or angioneurotic edema but for many years the patient had suffered from a vesicular, oozing dermatitis which developed during summer, on any skin surface that was exposed to the sun. During the winter she was entirely free. There was a history of stiffness of the fingers with, at times, swelling and tenderness of the joints. One year before she had taken mono-iodo-cinchophen for one or two days but had discontinued it because of gastric discomfort. Seven to ten days before the onset of the present illness she had again taken mono-iodo-cinchophen two capsules containing 0.25 Gm. each three times daily and had continued this medication up to the time she was first seen. There was no history

of any other internal medication and there had been no change in the diet or environment.

There was no history of eczema, asthma or hay fever nor any dermatoses in the family. The husband and one son are both living and well.

The patient was well developed and well nourished and apparently in good health. The general physical examination including the respiratory and the cardiovascular systems was negative. The blood pressure was 110 systolic and 80 diastolic. The liver and spleen were not palpable and there was no enlargement detectable by percussion. Abdominal tenderness was not present. The skin showed no icteric tint. The conjunctiva and mucous membranes were clear. Numerous discrete wheals 0.5 cm. in diameter, were scattered over the trunk and extremities and patches of erythema were present, particularly in the suprapubic and axillary regions. A test for dermatographism produced an erythematous streak but no welt was formed.

The mono-iodo-cinchophen was discontinued. The patient was given a saline purgative and in addition to local antipruritic applications she received 10 cc. of calcium gluconate intramuscularly and 1 Gm. of a proprietary preparation of acid calcium phosphate was given by mouth twice daily. For the first six days she also received 50 mg. of ephedrine sulphate by mouth morning and night.

Oct. 5 the urticaria became more severe. The wheals became confluent forming plaques from 2 to 3 cm. in diameter, they were most numerous about the neck, axillae, suprapubic region and across the shoulders. The skin of the palms and soles was thickened, tense and extremely pruritic and there was considerable edema of the vulva. It was necessary to give 10 mms. (0.6 cc.) of epinephrine hydrochloride solution (1:1000 dilution) on four occasions and colloid baths were ordered. During this time the patient complained of a feeling of heaviness in the stomach, nausea, complete loss of appetite, slight mental confusion and dizziness. October 6 she vomited a clear frothy fluid which was colorless. The stools were of normal color but the urine was scanty, odorless and dirty. A specimen for analysis was not obtained. October 7 the urticarial outbreaks became less frequent and less severe and the pruritus was much less marked. At this time patches of morbilliform erythema became more prominent and were present in the axillae, flanks and suprapubic region. October 9 a patch of papulovesicular dermatitis appeared between the breasts. During the next week, the cutaneous disturbances gradually subsided, the appetite returned and the gastric discomfort and vertigo disappeared. A fine, branny desquamation especially marked on the palm was noted October 15. Since that time the patient has felt entirely well.

October 27 percutaneous tests were applied to the extensor surfaces of both upper arms according to the technique described by Schoch.² Mono-iodo-cinchophen being insoluble in distilled water, the linen square was moistened and covered with an even layer of the powder before the patch was applied to the left arm. The dry powder was used on the right arm. A scratch test was performed on the flexor surface of the left forearm the dry powder being applied. Both percutaneous tests were negative after twenty-four, thirty-six and forty-eight hours. The scratch test showed more erythema than did the control and there was slight infiltration at the site but no wheal developed and the test was considered negative.

COMMENT

It is presumed that this case of generalized urticaria and toxic erythema resulted from the ingestion of mono-iodo-cinchophen because that is the only medication that the patient had received, because she had never before had an urticarial attack and because there were no dietary nor environmental factors that could be incriminated. The cutaneous eruption might be interpreted as the result of a specific hypersensitivity to the drug to some product of its oxidation in the body or as a secondary reaction following slight damage to the liver and gastro-intestinal tract with absorption of toxic products. The negative results of the percutaneous tests were anticipated in view of the statement of Sulzberger³ that this test is usually

positive not in the urticaria but rather in cases of dry, erythematous eruptions from drugs, such as arsphenamine dermatitis. The negative result of the scratch test suggests that the urticaria was not an allergic reaction due to a specific agent, in this case mono-iodo cinchophen, as has been pointed out by Jadassohn.⁴ Because of this fact as well as the fact that the constitutional symptoms were sufficiently prominent to give evidence of gastric and possibly hepatic disease, it is believed that the erythema and urticaria were due to the absorption of toxic substances from the liver and gastro-intestinal tract.

SUMMARY

1 In a case of urticaria and toxic erythema in a patient taking mono-iodo cinchophen, nausea, vomiting, anorexia and vertigo were present but there was no jaundice and no clinical evidence of pathologic changes in the liver.

2 The scratch test and percutaneous test with mono-iodo-cinchophen were negative.

3 It is believed that the cutaneous eruption resulted not from a hypersensitivity to the drug as such but rather from toxic substances absorbed from the liver and gastro-intestinal tract.

FROZEN SECTIONS PREPARED BY USE OF DRY ICE *

JANIER W. LINDSAY, M.D., E. CLARENCE RICE, M.D., AND
M. A. SELINGER, M.D., WASHINGTON, D. C.

The value of frozen sections of pathologic tissue is being more and more emphasized and is becoming more generally recognized as the application of this form of examination is demonstrated in many of the large clinics and as it is familiarized by frequent and constant employment in one's own laboratory.

Modification of the technique with resulting simplification of the process and reduction of cost will we believe, lead to even more extensive usefulness and remove some of the objections that doubtless occur to many laboratory men. A departure from the standard type of apparatus, with the purpose of eliminating some of the difficulties, is offered.

The special equipment which may be readily attached to any microtome and which is shown in the accompanying illustration consists of an ice chamber with a freezing plate and a plunger with which the ice may be brought into contact with or released from the plate. The freezing material is the commercial dry ice¹ readily obtained from ice cream packers at a small cost. A block of this substance weighing 5 pounds may be kept in the cardboard container in which it is delivered and at ordinary room temperature for forty-eight hours. By the use of thoroughly insulated containers it is hoped to extend the life of a supply beyond this time. However, with this time limit it is seen that many possibilities for preparing sections by the freezing method at long distances from the hospital or even from the city are offered. No other equipment than the fixing and staining materials, a small block of 'dry ice' and a small portable microtome are necessary. The entire apparatus and materials may be carried in a small case.

The large cumbersome liquid carbon dioxide tanks with the difficulty of mounting, dismounting, setting and manipulation during the freezing are entirely eliminated. The familiar blast of the gas escaping from the tank is replaced by complete silence of operation.

The ease of transportation, the absence of noise, the small space occupied, the rapidity of freezing, and ready control of

the hardness of the specimen seem to us to commend the proposed technique to the plan, which is growing in favor, of freezing sections in the operating room so that the results of the examination may be coordinated with the clinical picture and demonstrated at once to the attending physician and surgeon.

The simplicity of the apparatus and low cost of the freezing material will make it readily possible to utilize the frozen section for an unlimited number of specimens, including those from necropsies.

H-O OATS (QUICK) NEW STYLE

Manufacturer—Heeler-H-O Company, Inc., Buffalo, N. Y.

Description—Oat flakes lightly toasted, cut small and rolled thin to permit quick cooking.

Manufacture—Good grade sound oats are cleaned of all foreign material. The cleaned oats in their natural hull covering are mildly toasted in open pan kilns for four hours. The toasted oats are cooled, de-hulled between stones, and the hulls separated from the oat groats. The groats are cut into small particles by cutting machines. The cut groats are steamed flaked between rolls, cooled and packed in label wrapped cartons. The oat flakes contain practically all of the three portions of the oat—bran, germ and endosperm.

Chemical Composition—

	(proximate analysis)
Moisture	5.0%
Ash	2.0%
Fat (ether extract)	7.1%
Protein (N x 6.31)	15.2%
Crude fiber	1.1%
Carbohydrates (by difference) other than crude fiber	66.2%

Calories—

3.91 per gram
111.0 per ounce
1.76 per pound

Ingredients—Vitamins B (complex) and E.

Claims of Manufacturer—H-O Oats (Quick) New Style is a quick cooking breakfast cereal when prepared according to the label directions is well cooked in two to three minutes. H-O is pan-toasted, has a nut brown color, a distinctive baked-in toasted flavor and cooks up firm and meaty and not sticky and pasty. The pan-toasting toasts more than do the processes usually accorded oats and gives a distinct and different flavor.

This cereal supplies abundant food energy, valuable protein, vitamins B (complex) and E, phosphorus and iron.

⁴ Jadassohn, W., Klin. Wchnschr., 19, 133.
From the Pathological Laboratory, Carl-Neuberg Hospital.

Apparatus for utilizing dry ice in preparation of frozen sections. A, gridded freezing plate (metal); B, dry ice chamber (fiber or wood); C, plate carrying ice (fiber or wood); D, clamp and post for attaching to microtome (metal). The apparatus is about twice as large as the picture.

ADVERTISING AND THE DOCTOR

Although the great American god Advertising apparently controls most of our activities and our interests, it has not thus far succeeded in gaining a complete overlordship in the field of medicine. True, the use of the health claim for the advertising of antiseptics, tooth pastes, foods and most household utilities has become a popular means of approach to the 'health-conscious' public. True, some clinics still promote their services to the indigent and the middle class by extensive announcements in the public press, for this however the plea of holy charity is used in extenuation. Again and again advertising agents seeking some new outlet for the practice of their art have developed campaigns to be financed by medical societies or by individual physicians with a view to placing the wares of the medical profession before the public, as the services of musicians, plumbers, electricians and bakers are advertised. Thus far few medical societies of importance have succumbed to the lure of such promotions.

Several years have passed since various county medical societies in one of the states purchased space to announce some well established facts regarding the prevention of disease. The evidence thus far available indicates that the campaign was not particularly successful in enlightening the public or in bringing increased financial returns to the members of the societies that paid for the campaign. Not long ago several county medical organizations combined with some philanthropic organizations to promote a newspaper campaign for the advancement of the periodic health examination by the family physician, and incidentally by several pay clinics. As far as any information is available there is little evidence that this campaign resulted in any clearly defined saving of lives, any decreased morbidity or any increase in the emoluments of the medical profession.

Some time ago, a promoter of advertising by county medical societies submitted to the Judicial Council of the

American Medical Association a series of advertisements with a view to finding out whether or not publication of such announcements would be considered an ethical procedure. Holding strictly to its function of passing on questions of ethics, the Judicial Council informed the advertising agency that it could see nothing fundamentally opposed to the principles of ethics in that series of announcements. The Judicial Council did not, of course, express the individual views of its members as to whether or not in their opinions such an advertising campaign was advisable or likely to be of service either to the medical profession or to the public.

Reports have reached the headquarters office of the Association to the effect that the compilers and salesmen of this series of advertisements have been visiting newspaper editors in various communities with the suggestion that they induce the county medical society to purchase space for the publication of these announcements. It is reported that some of these salesmen have conveyed the impression that their entire plan has been officially approved by the American Medical Association. This is not true. It is also reported from some sections that officers of the medical society have been informed that publicity would not be given to medical affairs in that community unless the medical society purchased the space for the announcements that have been mentioned. Thus what might be called a diplomatic manner of 'bringing pressure to bear' has been used in an attempt to force the medical society into such expenditure of its funds.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION feels that expenditure of the funds of a county medical society for advertising announcements planned primarily to teach the facts of preventive medicine is not a proper expenditure for a medical organization. Medical education of the public is just as much a function of the press as education in the rules of contract bridge, the technique of golf or the proper training of children. The threat of any newspaper that it will omit scientific news of importance in the field of medicine unless physicians purchase advertising space is an idle threat. Any newspaper worthy of the name must publish scientific news. The vast majority of competent editors are convinced that few other news items are of equal significance at the present day. The newspaper that is dominated in its news columns by its advertising department is on the road to ruin.

The question of the publication of newspaper advertisements by county medical societies would appear not to be so much a question of medical ethics as one of common sense in the field of business. From this point of view, the burden is on the promoter to prove that the spending of money for such announcements provides an adequate return to the purchaser of the announcement, or to the public that such announcements are planned to serve.

PANIMMUNITY

Demonstration of the polio-myeliticidal action of normal adult human serums¹ has raised anew the question as to whether or not such adult immunities are due to previously unrecognized specific infections. The question is of more than academic interest. On its solution depends the interpretation of many epidemiologic data and the feasibility or desirability of many proposed quarantine and vaccination methods. Arguments against previous subclinical infections as a cause of such adult immunities have been drawn from a study of Eskimo children. These isolated children apparently develop the same percentage immunity to diphtheria toxin as children in more crowded environments, diphtheria bacilli being practically unknown in arctic regions.

The most suggestive data, however, are those recently published by Friedberger, Bock and Furstenheim² of the Hygienic-Immunologic Institute, Berlin. These investigators studied the appearance in growing children of "antibodies" against such noninfectious agents as sheep and rabbit erythrocytes, antigens that presumably never came in contact with their internal tissues. They report that the umbilical blood of new-born children contains no recognizable trace of these "antibodies" but that by the end of the first year 20 per cent of all children yield hemolysins and agglutinins for these erythrocytes. This proportion is increased to 60 per cent by the fifth year and to nearly 90 per cent by the tenth year. The hemolysins and agglutinins remain at a relatively high titer throughout adolescence and early adult life and then gradually decrease, giving quantitative curves approximately the same as those previously published for the apparently spontaneous immunization of the adult population to diphtheria and scarlet fever.

Friedberger and his co-workers argue from this parallelism that defensive antibodies are formed and increased in growing children as a result of a general maturation law and that observed mass immunizations to diphtheria, scarlet fever, poliomyelitis and other transmissible diseases are not necessarily due to previous subclinical infections.

This conclusion is of such far-reaching practical significance that a possible error in their logic must not be overlooked. Mutton and rabbits are common articles of European diet. Food proteins are but partially denatured by cooking. Gastro-intestinal absorption of undigested food proteins has been adequately demonstrated by American investigators³ a fact wholly over-

looked by the German investigators. Food proteins are secreted also in mother's milk.⁴ In order to prove that mutton and rabbit "antibodies" are due to a spontaneous maturation panimmunity, it would be necessary for Friedberger and his co-workers to prove that the formation of these "antibodies" is not specifically stimulated by gastro-intestinal absorption of habitual foods.

In spite of this criticism, there are many immunologists who prophesy that a spontaneous maturation panimmunity eventually will be proved.

MOTTLED ENAMEL IN SEGREGATED POPULATIONS

The laboratory and with it the experimental animal frequently play a large part in the determination of the etiology of disease. In some instances the causes of abnormalities have been detected without the help of studies on lower animals. In such investigations dependence is usually placed on vital statistics concerning the groups involved, as was the case with simple goiter and silicosis, on rare occasions, as in the study of the causative factor of yellow fever, opportunity for observations on human beings is afforded. A recent study by Kempf and McKay⁵ of the United States Public Health Service on the cause of mottled enamel in the teeth of certain groups of people in a rather circumscribed locality deserves attention because of the unique opportunity for controlled observations and the directness with which the cause was attributed to the water supply.

The condition of mottled enamel on the teeth is not new or even unusual, as it has been previously observed in various parts of the world. Only infrequently are the temporary teeth affected. The enamel of a mottled tooth may appear a flat, opaque white, may be stained yellow, brown or black, or, in addition to these changes, may have a corroded surface. The brown stain, when present, appears on the labial surface of the upper incisors and bicuspids. The fundamental defect seems to be both in the enamel rods of the tooth and in the cementing substance between them, the former showing an altered shape and the latter being absent. In any attempt to elucidate the etiology of this condition, cognizance must be taken of the fact that the first molars, incisors and first bicuspids are calcified between the first and the eighth years, while the rest of the teeth except the third molars are calcified from the seventh to the ninth years of age. The appearance of mottling in the various teeth therefore is the effect of influence operating some years before the observation is made.

Kempf and McKay studied the situation in a town in Arkansas established by a mining company in 1901.

4. Dally, H. H. The Question of the Excretion of Food Proteins (the White) in Women. *Med. J. London* 1931 (1): 11-13.
5. Kempf, C. A. and McKay, I. S. Mottled Enamel in a Town in Arkansas. *Pub. Health Rep.* 15: 2423 (Oct.) 1940.

The evidence was gathered by examination of the children in the school, from questionnaires filled out by the children, and from the employment records of the mining company. The original water supply consisted of surface wells and springs, but as the population increased this was supplanted by several deep drilled wells from which the water was piped into the homes. However, many of the families continued to use spring water because of the disagreeable alkaline taste of the deep well water. It was found that all the cases of mottled enamel appeared after the deep well water was provided. The oldest child examined and possessing the dental defect was born about the time the new water system was instituted. A close correlation was shown between the presence or absence of mottled enamel and residence or nonresidence in the town during the calculated period of enamel formation. In children whose enamel was laid down elsewhere mottling was absent, indicating again that it arises only during the calcification of the teeth. Indeed, one child who had lived in the town during the last period of calcification of the incisors, showed only a narrow band of mottling near the gums, while the rest of the tooth was normal, the second molars and cuspids, calcified while the child lived in the town, were entirely mottled. Children attending the school but living out of the town or consuming spring water showed normal enamel.

The data indicate rather strikingly that some factor connected with living conditions strictly within the town is responsible for the mottled enamel. That meteorological conditions can be ruled out would seem reasonable from the fact that children living in the immediate vicinity of the town are not affected. For the same reason, as well as from the fact that the disease appears among the children of both well-to-do and poorer families, the investigators conclude that a dietary factor can be eliminated as the cause. On the basis of the evidence it appears that the drinking water is responsible for the peculiar dental defect, and on these grounds a new domestic water supply has been provided. However, comparative chemical analyses of the two waters have thrown no light on the possible cause of the mottled enamel. It is pointed out that within six or seven years another survey will show whether or not the change has eradicated the disease here as has been done elsewhere by similar measures.

Quite aside from the general health aspect of the situation, the uniform occurrence of mottled enamel in the localized sections presents a unique problem in nutrition. Some obscure factor, not detected by chemical or bacteriologic analysis, operating over relatively long intervals of time during the periods of calcification of the teeth, causes the defect. At present it is thought that the factor occurs in the deep well water rather than in the surface waters or food. Almost every child born and reared in such an endemic

region is sure to be disfigured to a greater or less extent by mottling of the enamel. The solution of the problem is therefore imperative. Modern studies in nutrition have demonstrated the great potency of factors in the dietetic environment which are present in minute traces and which the conventional methods of analysis have failed to detect. The studies here discussed have gone a long way in discovering an analogous factor in the etiology of mottled enamel.

UNLAKED BLOOD FOR CHEMICAL ANALYSIS

One of the characteristics of modern medicine is the success with which sciences not primarily biologic have been employed in the expansion of the knowledge of disease and in the increase in facility and accuracy of diagnosis. Both chemistry and physics play an important part in current medical thought and practice. Internal medicine, especially, has appropriated the device of blood analysis and has profited immensely by so doing. The rationale of the use of such analytic chemical data is based on the conception of the blood as the primary transporting system of the body carrying not only nutrients to the cells but, what is more significant from the diagnostic point of view, removing waste products from the site of formation to the excretory organs. An abnormal concentration of metabolites can thus be attributed to excessive production or to defective elimination. In general, the determination for the constituent in question has been carried out on the protein-free filtrate from laked whole blood.

That such procedure is theoretically justified has recently been questioned by Folin and Svedberg,¹ who point out that, practically, the inclusion of the contents of the red blood corpuscles in the material to be analyzed leads to difficulties of analysis and, as a consequence, to obscure and misleading results. On the basis of a large number of comparative analyses on laked blood, unlaked blood and plasma, these investigators have come to the further conclusion that many of the accepted statements concerning the partition of soluble constituents between corpuscles and plasma are untenable. It was shown, for example, that the ratio of content in corpuscles to that in plasma for sugar is 60:100, for urea 80:100, and for uric acid 22:100. It was also observed that amino-acid nitrogen is much more abundant in the plasma than in the unlaked corpuscles, a fact not in harmony with previously published results.

The enormous number of analyses of blood carried out as part of the usual hospital laboratory routine together with the great reliance placed on the results, render the searching evaluation of the methods employed of huge importance. It is pointed out by the Harvard

¹ Folin Otto and Svedberg Andrea J Biol Chem 88 715 (Oct) 1930

investigators that, whereas with laked whole blood the contents of the red cell are known to interfere with certain of the determinations and consequently to affect the results, through the use of unlaked blood such disturbances are eliminated. For instance, with laked blood the partition of the nonprotein nitrogen always resulted in a fraction of unidentified composition usually called "undetermined", with unlaked blood, the sum of the nitrogen from urea, uric acid, creatinine and amino-acids equals the total nonprotein nitrogen. When the contents of the corpuscles are analyzed with the plasma for sugar, the values for the fermentable material and the reducing substance do not coincide, when unlaked blood is used, the nonfermentable, reducing component of the cells is eliminated and the two methods for determining sugar yield similar results.

As usually happens when improved methods are devised, not only must previous conceptions be revised but it is necessary to supplant analytic data already existing. Furthermore, it might be expected that the diagnostic value of the improved methods would be enhanced, in fact, the authors state on the basis of their experience that "unlaked blood cannot fail to be more useful than laked blood in clinical applications of blood analysis."

Current Comment

BOTULISM AND HOME CANNING

Again attention must be directed to an outbreak of botulism from home canned vegetables, presumably canned by the so-called cold pack process. In this, the first outbreak to be recorded for 1931, the causative food epidemiologically was a salad made up from two glass jars of a mixture of home canned string beans, peas and carrots. The outbreak occurred in Grafton, N. D. following a party given on the night of January 29. Seventeen persons attended the party, twelve are dead, probably all who showed symptoms of botulism. Heretofore, home canned string beans have caused outbreaks of botulism in excess of any other food. Home canned string beans, even when mixed with carrots and peas, canned by the cold pack process, are a potential menace to the health. They should always be boiled before being served. Departments of home economics in agricultural colleges, universities and their extension divisions throughout the country should plan a vigorous educational campaign to prevent these deaths. Unfortunately many of the recipes for the home canning of vegetables antedate the present-day knowledge of botulism and with few exceptions no effort has been made to correct them. Admittedly it is difficult to reach those who are endangered by foods inadequately preserved in the home. Nevertheless the public should be told with unrelenting insistence that string beans and every nonacid vegetable may be rendered safe by sterilization for a sufficient time and temperature in a pressure cooker, by drying or by the

addition of a 10 per cent brine solution to the cold pack method. Enough information is now available to enable authorities to formulate definite rules to guide the home canner. Most of these facts were fully brought out in the original report of the California Botulism Commission.¹

THE HOSPITAL AND THE PATIENT

Social service is an important feature of the modern hospital. Patients may need something more than patience in the sometimes slow operations of the laws of the natural and physical sciences under the guidance of an enlightened physician or a talented surgeon. In an address before the American Association of Hospital Social Workers, a sympathetic critic² recently pointed out that amid the medical revolutions of the past centuries with their increasing mass of scientific knowledge the traditional meaning of the word hospital has been largely forgotten. It meant a place of hospitality for those in need of shelter and maintenance, and it was called a "hospital" because those sheltered there were considered, in the Latin, to be *hospes*, or guests. The spirit that makes a patient a guest and the hospital his host should be deeply inculcated. The patient is not merely a "scientific phenomenon" that demands time-consuming attention from a physician, but also a social being. Enlightened social service can do much to 'make a hospital a place of hospitality, to insist upon the point of view that the ill human being in hospital is a guest, and not merely a patient."

Association News

ABSTRACT OF MINUTES OF MEETING OF BOARD OF TRUSTEES HELD IN CHICAGO, FEB 19 AND 20, 1931

The Board of Trustees met in Chicago on Thursday and Friday, Feb 19 and 20, 1931.

REPRESENTATIVE TO NATIONAL CONFERENCE ON NOMENCLATURE OF DISEASE

Dr. Adrian Lambert of New York was appointed to represent the Association at the National Conference on Nomenclature of Disease.

REQUESTS FOR CONTRIBUTION TOWARD EXPENSES OF THE MEETINGS OF OTHER ORGANIZATIONS

The Board declined to make appropriations toward the expenses of meetings of other organizations, in the belief that this is not the province of the Association.

REQUEST FOR INFORMATION AS TO PLACING OF FUNDS AVAILABLE FOR THE PURPOSE OF RENDERING ASSISTANCE TO HOSPITALS AND FOR THE ADVANCEMENT OF MEDICAL SCIENCE IN GENERAL

A request for information as to the placing of funds available for the purpose of rendering assistance to hospitals and for the advancement of medical science in general was given consideration. The Board signified its eagerness to cooperate in any undertaking of this nature for the general promotion of medicine and suggested that such funds be used for the improvement of hospitals in general through the American Medical Association rather than for improvement in specific practice.

REPRESENTATIVE TO MEETING OF BRITISH MEDICAL ASSOCIATION

Dr William S O'Neill Sherman of Pittsburgh was named to represent the Association at the meeting of the British Medical Association, to be held in Eastbourne, July 21-24

APPOINTMENT OF THIRD MEMBER OF COMMITTEE ON MOTION PICTURES

Dr Arno B Luckhardt was elected as the third member of the Committee on Motion Pictures. The personnel of this committee therefore is Dr Charles P Emerson of Indianapolis (chairman), Dr Carl Henry Davis of Milwaukee and Dr Arno B Luckhardt of Chicago

APPLICATION OF SERVICES OF DR W MCLELL MARRIOTT ON COUNCIL ON PHARMACY AND CHEMISTRY

The Board expressed its appreciation of the splendid service rendered by Dr Marriott on the Council on Pharmacy and Chemistry, and its regret that he felt constrained to resign

ELECTIONS

Nominations to fill vacancies on the editorial boards of the special journals on councils and on committees were considered, and the following appointments were made:

Drs Oscar M Schloss, E W Taylor, Dean Lewis, William Allen Pusey, John Herbert White, George L Shambaugh and James Ewing were elected to succeed themselves on the editorial boards of the *American Journal of Diseases of Children*, *Archives of Neurology and Psychiatry*, *Archives of Surgery*, *Archives of Dermatology and Syphilology*, *Archives of Ophthalmology*, *Archives of Otolaryngology* and *Archives of Pathology*, respectively

Dr J H Means of Boston was selected to succeed Dr George Dock on the editorial board of the *Archives of Internal Medicine*, and Dr Wilder Penfield of Montreal, Canada, was elected as a contributing editor on the editorial board of the *Archives of Neurology and Psychiatry*

Drs L B Mendel, L G Rowntree and Torald Sollmann were named to succeed themselves, and Dr Stanhope Brune Jones was appointed to succeed Dr W McKim Marriott (resigned), on the Council on Pharmacy and Chemistry

Dr Frederick J Genslen of Milwaukee was elected to succeed Dr Richard B Dillehunt (resigned) on the Council on Physical Therapy

Dr Ludwig Hektoen was appointed to succeed himself on the Committee on Scientific Research

REQUEST THAT THE ASSOCIATION SPONSOR AND DIRECT AMERICAN MEDICAL ASSOCIATION OF VIENNA

A request that the American Medical Association assume directorship and sponsorship over the American Medical Association of Vienna was refused, since it would not be possible, under the terms of the charter or under the provision of the Constitution and By Laws, for the American Medical Association to comply with the request

DECISION IN BRINKLEY BROADCASTING CASE

A record was made of the decision of the Court of Appeals of the District of Columbia affirming the decision of the Federal Radio Commission denying the Brinkley-Jones Hospital Association's application for renewal of its station license

REPRESENTATIVE TO SERVE ON SECTIONAL COMMITTEE OF AMERICAN STANDARDS ASSOCIATION

As one of the cooperating organizations that prepared the original standard on lighting of school buildings the Association has been asked to appoint a representative to serve on the Sectional Committee of the American Standards Association which will undertake a revision of that standard. The Board appointed as its representatives the Joint Committee of the American Medical Association and the National Education Association which has previously dealt with matters of this kind

BUREAU OF ECONOMICS

Tentative plans were adopted for the establishment in the near future of a Bureau of Economics

DISAPPROVAL OF REGISTRATION

Disapproval was expressed of bills S 5922 and S 5923 introduced by Senator Brookhart. The former is an effort to effect compromise and to prosecute criminals with the possibility of fine and imprisonment every physician or any one else violates the law with respect to the traffic in narcotic drugs, the latter makes it unlawful for a physician or surgeon to administer or prescribe narcotic drugs without information of the patient of his intention and conforming with various other restrictions that, if they are to be imposed at all, lie generally within the jurisdiction of the several states

MISCELLANEOUS

Appropriations were made to carry on the work of the various departments, councils and bureaus, as well as for the Committee on the Protection of Medical Research and the committees on scientific and therapeutic research

THE PHILADELPHIA SESSION

Headquarters Selected for Section on Obstetrics, Gynecology and Abdominal Surgery

The Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association will try the plan of designating a hotel as section headquarters for the Philadelphia meeting. The Hotel Walton has been selected for this purpose.

If you desire to stop at this hotel to facilitate meeting with other members of the section I kindly make reservation at once through Frederick S Bilde, Chairman of Committee on Hotel, Chamber of Commerce, Twelfth and Walnut streets, Philadelphia.

There is nothing obligatory about this plan as it is done solely with the idea of facilitating the association of members with others who have similar interests.

FRED L ADAIR, Chairman.

CONTRIBUTIONS FOR MEDICAL SALON IN PERSHING HALL

The sum contributed this week for the Pershing Memorial in Paris brings the total to \$2124.60. A list of those who have contributed during the current week follows:

Nelle S Noble MD Des Moines	May E Walker MD Piedmont
John F Haggerty MD Newark	Frank G Sanders MD, Fort Worth Texas
Frederick J Hierer MD, Cape May	Archib Crandell Greystone Park
Ramon A Aios MD Naguabo	M M Houcman MD New York
I R Woodward MD West Chester	J A Chittard MD Baltimore
Kalamazoo Academy of Medicine	Bertram M Bernheim MD Baltimore
Kalamazoo Mich	Carl B Herrmann MD Chicago
I C Spitzer MD East St Louis Ill	Samuel T Levethan MD New York
B P Levegood MD Bellwood	C I Swett MD, Wyncottkill
Robert H Ivy, MD Philadelphia	Frank L Culbert MD, North Stratford, N H

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a m on Monday, 10 45 on Tuesday, 9 15 on Thursday and 10 30 on Saturday, over Station WBBM (770 kilocycles or 389.4 meters)

The program for the week is as follows:

March 9	Mental Hygiene for Middle Life
March 10	That Indefinite Term Indigestion
March 12	That Important Preschool Period
March 14	The Proposed Home for One Legged Canary Birds

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays from 12 to 12 05 p m, Central Standard Time

The program for the week is as follows:

March 9	The Chinese Wall
March 10	How the Body Works—Respiration
March 11	How the Body Works—Circulation
March 12	The Body's Street Cleaning Department
March 13	Life's Most Vital Fluid
March 14	Training the Senses

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Bills Introduced—S 69 proposes to authorize the state treasurer to receive and disburse money given or provided to the state board of health by any person or agency, to enable the state board of health to engage in health demonstration work S 75 proposes to require every physician, surgeon, nurse or hospital attendant called on to treat any person for gunshot wounds, knife wounds or other material injuries that may have resulted from a fight, robbery or other unlawful act to notify immediately certain police authorities S 76, to amend the law with respect to the membership and functions of the state board of health, proposes to provide that the state board of health consist of the governor, the attorney general, the superintendent of public health and two resident practicing physicians, who shall be appointed by the governor from a list of five physicians presented by the Arizona State Medical Association

ARKANSAS

Bills Introduced—S 374 proposes to allow physicians to prescribe intoxicating liquor under the same general restrictions that appear in the Volstead Act S 399 proposes to regulate the practice of barbering

CALIFORNIA

Dr Porter Appointed State Health Officer—Dr Giles S Porter Los Angeles, was recently appointed state health officer and assumed his duties, January 29 Dr Porter has been assistant health officer of Los Angeles for many years He succeeds Dr Walter M Dickie, who has held the position since August, 1920 Dr Porter graduated from the Chicago Homeopathic Medical College in 1900

Bills Introduced—S 175 proposes to create the office of commissioner of medical and hospital service companies and to regulate and to provide for the supervision and licensing of medical and hospital service companies Such companies, apparently, are to be authorized to contract with individuals, families employees, associations, societies or employers to furnish medical, surgical or other form of treatment for sickness or injury, but they are to provide such treatment only through regularly licensed hospitals or institutions and only by persons regularly licensed to render such services S 358, to amend the narcotic drug act, proposes to provide that in any prosecution of a physician for a violation of the act, proof that the physician received, or had in his possession at any time, a greater amount of narcotic drugs than the record required by the act accounts for, shall constitute prima facie evidence of guilt A 1148 proposes to create a narcotic control board, which may establish such rules and regulations as it deems necessary to carry out adequately the enforcement of the act A 1147 proposes to establish a state narcotic hospital for the confinement, care, cure and rehabilitation of drug addicts A 1143 proposes to establish two institutions for the confinement treatment and rehabilitation of habit-forming drug addicts S 730 proposes to create a board of examiners for Christian healing and to regulate the practice of Christian healing The proposed license would permit the practice of Christian healing by prayer and anointment and imposition of hands S 463 proposes that after July 1 1931 all applicants for physicians and surgeons certificates shall in addition to present educational requirements present evidence of not less than one year's training in a hospital approved by the medical examining board

CONNECTICUT

Bills Introduced—S 127 to amend the law requiring hospitals to be licensed by the state department of health proposes to require the licensing of all hospitals except hospitals wholly supported by the state The present law exempts hospitals wholly or partly supported by the state hospitals for the insane, private tuberculosis sanatoriums receiving state aid and maternity hospitals H 303 to amend the law authorizing boards of education to require every child to be vaccinated before being permitted to attend a public school proposes to provide that if

the parents of any child conscientiously object to vaccination, their child may be admitted to school on the presentation of a conscientious exemption certificate S 213, to amend the medical practice act, proposes to provide that the provisions of the medical practice act shall not apply to licensed osteopaths, chiropractors or naturopaths H 984 proposes to provide that

Section 341 of the General Statutes does not apply to any one of the Jewish faith" Section 341 relates to the issuance of death certificates and provides that when death has occurred from certain communicable diseases no person other than a licensed embalmer shall have charge of the body H 415 proposes that each person detained in a state or private institution for the mentally deficient shall be examined at least once each year under the direction of the state department of health S 496 seeks to allow the medical, eclectic and homeopathic examining boards to issue, without examination limited certificates authorizing registration to practice medicine in specified hospitals "or other institutions" to persons who have creditably completed the required course of study in a legal and reputable medical college H 655 proposes to provide that all public health activities shall be under the state department of health H 875 proposes to restore to Isidor Yochelman of Boston, formerly of Bridgeport, the right to practice medicine H 897 proposes to provide that any physician who shall demand and receive an excessive fee for professional services shall be fined not more than \$100 H 901 proposes to abolish the office of coroner H 981 proposes that any person who is a duly licensed pharmacist in any other state may be licensed to practice pharmacy in Connecticut in accordance with such rules and regulations as may be prescribed by the pharmacy commission H 978, to amend the medical practice act, proposes to require all practitioners of the healing art to register annually, but does not require an annual fee

DELAWARE

Bill Introduced—H 169, to amend the workmen's compensation act, proposes, among other things, that the cost of such surgical, medical and hospital services as the condition of the injured employee requires shall not exceed \$150

GEORGIA

Health Units Established in Drought Area—Dr Thomas F Abercrombie, state commissioner of health, recently announced that three full time health units would be established in Georgia through drought relief funds of the federal government The work will be under the supervision of Dr Millard E Winchester, director of county health work state board of health The unit in health district number 1 composed of DeKalb, Wilkes and Chattooga counties, will supplement the work of the full time health unit that has been functioning for several years in Wilkes County, headquarters will be at LaFayette A unit in health district number 2 composed of Catoosa, Whitfield, Murray and Gordon counties will supplement the work of the full time nurse maintained by Whitfield County, with headquarters at Dalton One mobile field unit will act as a flying squadron and will be dispatched to all parts of the state where there is no organized health work it will have its headquarters at Atlanta Two sanitary engineers are being added to the staff of the state board of health for general work over the state The amount to be expended in Georgia by the federal authorities has been estimated at between \$30,000 and \$35,000

ILLINOIS

Bills Introduced—H 293 proposes to exempt practicing nurses registered under the provisions of the Illinois Nursing Act from jury service H 301 proposes to make it unlawful to sell any preparation containing wood alcohol methanol or methyl alcohol unless the container in addition to being labeled as now required by law contains the following statement in letters not less than one eighth inch in height Warning Wood alcohol (methanol or methyl alcohol) is extremely poisonous and may cause blindness or death if it enter the body through the mouth, by skin absorption or by inhalation of vapors H 311 proposes to provide that in case of any death occurring without medical attendance it shall be the duty of the undertaker to notify the coroner of the death and the coroner shall then make an investigation as to the cause of death

Personal—Dr Roy O Hawthorne Monticello has been appointed managing officer of the Kantake State Hospital to succeed the late Dr George S Edmondson —Dr William Thomas McLenn Maroa was the guest of honor at the meeting of the Decatur Medical Society February 17 in celebration of

his completion of fifty years in the practice of medicine. His son Dr. Franklin C. McLean, director of clinics and professor of medicine, University of Chicago, was the principal speaker and reviewed medical progress during the past fifty years. — Dr. Ott L. Pelton has retired after fifty-eight years in the active practice of medicine in and near Elgin.

Chicago

Serum Center Established—A department to be known as the Samuel Deutsch Convalescent Human Serum Center has been established at Michael Reese Hospital with funds provided by the children of Mr. Deutsch. It will supply special human serum to the Chicago district for the treatment of various infectious or contagious diseases and especially for the treatment of infantile paralysis. It is said to be the first serum center to be established in the state. The comparative figures for the number of cases of infantile paralysis in Illinois were 410 in 1930 against 88 in 1929. The serums are to be obtained only from patients who have recovered from various diseases and whose serum has been shown to prevent disease in patients who have been exposed to similar infection. Cooperating with the new serum center the Illinois State Board of Health will distribute convalescent serum. Drs. Sidney O. Lewinson and Leo Zimmermann are assisting in this work.

Lectures by Professor von Groer—Dr. Franz von Groer, director of the pediatrics department, University of Lemberg, Poland, who is the Theodore B. Sachs visiting professor at the University of Illinois College of Medicine, has been lecturing at the university since February 14 and will continue until March 14. Among others he addressed a joint meeting of the Chicago Tuberculosis Society and the Chicago Medical Society, February 25 on "Diagnosis, Prognosis and Treatment of Tuberculosis in Childhood." He delivered an afternoon lecture on the same day under the joint auspices of the Institute of Medicine of Chicago and the University of Illinois Department of Experimental Medicine on "The Esophagetic Importance of the Wheel and Its Relation to Immunity and Hygiene." The Theodore B. Sachs Memorial Fellowship has been established at the University of Illinois College of Medicine through a grant from the Chicago Tuberculosis Society.

INDIANA

Bills Introduced—H. 522 proposes to make it unlawful for any person to possess any opium, coca leaves, cannabis indica, or cannabis sativa, loco weed or any salt or derivative of any of them, except for strictly medical purposes. H. 480 proposes that it shall be unlawful for any city of 200,000 or more to locate or maintain any hospital for the treatment of infectious or contagious diseases within 1,500 feet of any public or private hospital now erected or in the course of erection. S. 284 proposes to authorize the appointment of county, city and district health commissioners.

IOWA

Dinner to Dr. Biering—Dr. Walter Lawrence Biering, Des Moines, for many years secretary of the Federation of Medical Boards of the United States, is to be the guest of honor at a dinner given by the Des Moines Medical Library Club, March 7. Dr. Biering is a past president of the Iowa State Medical Society and of the Iowa State Board of Health; he was for several years a member of the faculty of the State University of Iowa College of Medicine and later of Drake University. In 1921 he was made an honorary member of the Royal College of Physicians of Edinburgh in recognition of services in connection with reciprocity in medical education and licensure between Great Britain and the United States.

KANSAS

Bills Introduced—S. 340 and H. 577 to amend the medical practice act propose that persons holding certificates of the National Board of Medical Examiners may, at the discretion of the board, be granted licenses to practice medicine, without examination. S. 341, to amend the medical practice act proposes that the fee for reciprocal registration shall be fixed by the board but shall not be less than \$25, and if a certificate on reciprocal registration is denied, \$10 of the fee shall be retained by the board. S. 342 proposes to create a board of physiotherapy examination and registration and to regulate the practice of physiotherapy, defined as the use of natural forces in the treatment of disease. Apparently no exception is made in favor of licensed physicians. H. 582 proposes to authorize certain rural high school boards to employ a registered nurse.

MARYLAND

Bills Introduced—S. 102 to amend the dental practice act proposes to provide (1) that no person shall practice dentistry under any name except his proper name, (2) that it shall be unlawful to use the name of any company, association, corporation, trade name or business name in connection with the practice of dentistry and (3) that any one who shall act or be himself out as manager, proprietor, operator or conductor of a place for performing any dental operation or service pertaining to the human teeth, jaws or mouth shall be deemed to be practicing dentistry. H. 149, to amend the pharmacy practice act, provides that nothing in the act shall be so construed as to make unlawful the sale or display by general merchant of any proprietary or patent medicines or the sale by general merchants of commonly used household or domestic remedies, in original unopened packages, provided that such household or domestic remedies are clearly labeled with the ordinary name of the article contained therein and the name of the manufacturer or distributor thereof. H. 150 to amend the pharmacy practice act, proposes to discontinue the registration of assistant pharmacists. H. 168 proposes to provide for exempting the building, equipment and furniture of hospitals, asylums and other charitable and benevolent institutions from the payment of any assessments for the opening, grading and paving of any road or street.

MASSACHUSETTS

Speech Clinic Licensed—It is reported that the state department of health has licensed "The Medical Speech Clinic" in Boston, of which Dr. Walter B. Swift is director. The clinic which gives free treatment in cases of speech defect, is believed to be the first speech clinic in the United States to have a state license.

Bills Introduced—H. 494 proposes to accord liens to hospitals treating persons injured in accidents, on any settlements or judgments obtained by the injured persons by reason of the injuries. H. 595 to amend the pharmacy practice act, proposes to allow the sale of proprietary medicines, under the supervision of the board of pharmacy, by stores not less than a mile from a registered drug store.

Society News—The Southbridge District Medical Society was organized, January 7. Dr. Joseph G. E. Page was elected president. Dr. George Webster, vice president and Dr. Theodore L. Story, secretary. —Dr. DeWitt G. Wilcox addressed the New England Physical Therapy Society, February 18, in Boston on diathermy in gynecology and Dr. Benedict F. Boland on ionization of the cervix uteri by high frequency currents. —Dr. Joseph C. Aub, Boston, addressed the Harvard Medical Society, Boston, February 10 on "The Relation of Calcium Metabolism to Internal Medicine." —Dr. Augustus Riley, Boston, addressed the Belmont Medical Society, February 27, on "Value of Pyclograms as an Aid in Diagnosis."

MINNESOTA

Bill Introduced—H. 683 proposes to forbid the sale or serving of lunches or meals in rooms in which drugs are sold.

Society News—Dr. Chas. Ray Murray, New York, addressed the Minneapolis Surgical Society, February 4, on delay and nonunion of fractures. —Dr. Horace Newhart, Minneapolis, spoke on diseases of the mastoid before the Rice County Medical Society, Faribault, February 3. —Dr. James B. Carey, Minneapolis, discussed gastro-intestinal lesions at the Washington County Medical Society, Stillwater, January 13.

MISSOURI

Health at St. Louis—Telegraphic reports to the U. S. Department of Commerce from eighty-one cities with a total population of 36 million for the week ended February 14, indicate that the highest mortality rate (241) was for St. Louis, and that the mortality rate for the group of cities was 14. The mortality rate for St. Louis for the corresponding week last year was 168 and for the group of cities 134. The annual rate for eighty-one cities for the seven weeks of 1931 was 142 as against a rate of 132 for the corresponding weeks of 1930. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population, may tend to increase the death rate.

Society News—Dr. Emmett P. North, St. Louis, was elected president of the Medical Association of the Missouri Pacific Lines at its second annual meeting, St. Louis, January 30-31 and Dr. Henry J. Scherck, St. Louis, secretary. —Drs.

Caryl R. Ferris and Frederick C. Narr, Kansas City, among others, addressed the Jackson County Medical Society, February 24, on "Periarthritis Nodosa."

Bills Introduced—H 383 to amend the dental practice act, proposes to provide after 1935 for the appointment by the governor annually on October 16 of one member of the Missouri dental board, whose term shall be five years. Under the present law the terms of all members expire at the same time. H 390 proposes that one of the members of the state board of health shall be a dentist. H 447, to amend the dental practice act, proposes to require the board of dental examiners to mail to every registered dentist, on or before September 30 of each year, a notice of the expiration of his or her license, and on the first of March to publish and mail to every registered dentist a printed list of the legally registered dentists. H 459 makes it a misdemeanor to go 'from house to house or upon the streets and highways soliciting an opportunity to treat the sick or fit eyeglasses.' S 308 proposes to repeal the workmen's compensation act. H 462 proposes to authorize the board of pharmacy to license as a pharmacist, without examination, any graduate of a reputable medical college who has had twenty years of medical practice, has dispensed his own prescriptions, and is at least 45 years old.

NEBRASKA

Bills Introduced—S 99 proposes to provide for the appointment of women physicians for the care and supervision of the women insane in state hospitals. S 203 proposes to amend the workmen's compensation act by providing compensation for disablement by occupational diseases. Such occupational diseases to be compensable, must be contracted by exposure in connection with employment and manifest themselves within three months after the termination of the exposure. S 202 to amend the workmen's compensation act, defines the terms "injury" and "personal injuries" to mean "only violence to the physical structure of the body and such disease and infection as naturally results therefrom. The said terms shall in no case be construed to include any contagious or infectious disease contracted during the course of employment or death due to natural causes." Such a definition inferentially, makes some occupational diseases compensable. S 217 to amend the workmen's compensation act authorizes the compensation commissioner to establish a schedule of medical, surgical and hospital fees, and further proposes that an employer shall not be liable for compensation during the period an injured employee refuses to avail himself of medical or surgical treatment furnished by the employer. S 362, to amend the pharmacy practice act proposes that for the purpose of the act 'drugs and medicines shall include all poisonous, dangerous or deleterious substances and preparations, for external or internal use recognized in the United States Pharmacopeia or National Formulary which are intended for the correction, mitigation or prevention of diseases of either man or animals, or any other poisonous dangerous or deleterious substances and preparations intended for a similar purpose, except patent or proprietary medicines.'

NEVADA

Bill Introduced—A 90 proposes a new act to regulate the possession, control, dispensing sale, prescribing and other traffic in opium or coca leaves, or any compound manufacture salt derivative or preparation thereof.

NEW JERSEY

Personal—Drs. Oliver R. Blanchard and Louis Franklin co-founders of the Fairmount Surgical Sanatorium, Jersey City, were given a testimonial dinner in New York, February 19 by colleagues and members of the staff. The occasion marked the twentieth anniversary of the founding of the institution.

Bills Introduced—A 207 proposes to create a board of naturopaths and to regulate the practice of naturopathy. Naturopathy is defined as that system of the healing art which uses and prescribes the use of the combined psychological, mechanical and material sciences of healing as taught in schools, institutes and colleges of naturopathy which shall include psychotherapy, mechanotherapy, hydrotherapy, electrotherapy, pneumotherapy, neopneumotherapy, physiotherapy, chromotherapy, corrective and orthopedic gymnastics, spondylotherapy, geotherapy, dietetics, biochemistry, phytotherapy and external applications. A 264 to amend the medical practice act proposes to make it mandatory for the state board of medical examiners to license without examination ex-convict men who were residents of

New Jersey on enlistment, but who have subsequently been licensed to practice medicine in other states. A 370 proposes to regulate the occupation of barbers and would authorize such practitioners to 'remove superfluous hair, warts, moles and other blemishes from the scalp, face, neck or upper part of the body.' A 313 to amend the dental practice act provides that any person duly licensed to practice dentistry in another state who has so practiced for at least three years and who has been a resident of New Jersey for ten years may be licensed without examination in New Jersey. A 349 proposes to add a chiropractor to the state board of medical examiners. S 170 proposes to make it unlawful to sell any food, drink, medicine or toilet preparation intended for human use or any antifreeze agent for motor vehicle radiators which contains wood alcohol, methanol or methyl alcohol. Sales for other purposes may be made only in containers labeled 'poison.' A 205, to amend the osteopathic practice act, proposes, among other things, (1) to authorize the issuance of licenses to osteopaths to practice major surgery, and to permit all licensed osteopaths to practice minor surgery and obstetrics without restriction, and (2) to require that reports and certificates pertaining to the public health, made by osteopaths, be accepted by the department to which they are made, as having the same force and effect as those issued by nonsectarian physicians. Licensed osteopaths may be examined for licenses to practice major operative surgery on showing (a) two years' internship in an approved osteopathic or medical hospital or (b) a two years postgraduate course in surgery in a reputable college of osteopathy or medicine, or (c) at least three years of actual practice in major surgery.

NEW YORK

Trichinosis Outbreak Reported—Fifteen cases of trichinosis were recently reported at Williamsport. Although eight or the fifteen persons affected were confined to hospitals, no deaths had been reported up to February 7. According to the U. S. Department of Agriculture the outbreak was traced to the eating of raw or improperly cooked pork infested with trichinae.

Personal—Dr. Elizabeth B. Thelberg, resident physician at Vassar College, Poughkeepsie, recently retired after a service of forty-three years. Dr. Thelberg was for many years chairman of public health in the American Council of Women and more recently chairman of public health in the International Council of Women. She is a director of the American Women's Hospitals and has been decorated by France and Serbia for her work in connection with this organization which maintains hospitals and clinics for the destitute in various foreign countries supported by voluntary contributions. —Dr. Hugh S. Gregory, who has been connected with the Binghamton State Hospital for twelve years, has been appointed superintendent of Newark State School for Mental Defectives to succeed Dr. Harry A. Steckel.

Bills Introduced—S 837 and A 1158 propose to authorize the commissioner of health to establish and maintain tuberculosis hospitals in each sanitary district. S 769 and A 1066 propose to authorize the establishment of the Marcus division of the Utica State Hospital as a separate institution within the department of mental hygiene to be known as the Marcus State Hospital. A 1187 proposes to require asylums and hospitals in cities, villages, towns and fire districts having a central fire alarm station to be equipped with fire alarm boxes. A 1218 proposes to regulate the practice of barbering. A 1277 and S 915 to amend the medical practice act propose to provide that a license to practice osteopathy shall not entitle the holder thereof to perform any surgical operation involving incision for the opening of a natural body cavity for the removal of cancer for the amputation of an extremity or an appendix or for the removal of any gland or organ or part thereof of the human body. The present law does not permit osteopaths to administer drugs or perform surgery with the use of instruments.

New York City

Outbreak of Psittacosis—A shipment of six parrots which arrived in New York from Cuba Dec. 31, 1930, is blamed for an outbreak of psittacosis affecting five members of a family in Brooklyn. One person died January 18 of bronchial pneumonia. Psittacosis was suspected after four others became ill and after it was learned that they had been in contact with a parrot in the house in which the man died. New paper report, February 12, indicated that the disease was under control. All the birds were traced, two having been consigned to the family that developed psittacosis. The ban imposed by the U. S. Public

Health Service on the importation of parrots was lifted in October 1930. No change will be made in the restrictions if no further outbreaks occur, officials stated.

NORTH CAROLINA

Bill Introduced—H 294 proposes to require the annual registration of chiropractors and the payment of an annual fee of \$10.

Hospital News—The Lowrance Hospital was recently opened at Mooresville. It was erected at a cost of \$125,000, of which \$10,000 was donated by the Duke Hospital Foundation.

Personal—Dr. William I. Hill, Albemarle, has been appointed full time health officer for Stanly County. Dr. Zebulon A. Moschley, Kinston, has been appointed full time health officer of Lenoir County.

NORTH DAKOTA

Bill Introduced—H 259 proposes to make it unlawful to sell any food drink, medicine or toilet preparation or any anti-freeze agent for motor vehicle radiators containing wood alcohol or methyl alcohol. Sales for other purposes may be made only in containers labeled "poison."

OREGON

Bills Introduced—H 259 proposes a new pharmacy practice act. This bill apparently would prohibit licensed physicians and surgeons from dispensing or administering drugs and medicines except in an emergency. H 346 proposes to authorize the establishment of county boards of health to consist of one member of the county court, the county school superintendent, the mayor of the largest city of the county and one licensed physician. S 173 to amend the narcotic drug act proposes among other things that wherever the words "narcotic drugs" are used in the act they shall mean opium, morphine, codeine, cocaine, heroin, or any other of their salts or derivatives. Cannabis indica shall mean cannabis indica, cannabis sativa, Indian hemp, hashish or marihuana.

PENNSYLVANIA

Bills Introduced—S 117 proposes to authorize the county commissioners of any county and the corporate authorities of any borough located within such county to erect joint county and borough buildings to be used for hospital purposes. S 123 proposes that the children's society in each county may, without first obtaining the consent of any parent or guardian, legally assume responsibility for such emergency surgical operations as are pronounced necessary by attending physicians and surgeons for the health and comfort of children who are wards of the Children's Aid Society. H 580, to amend the workmen's compensation act, proposes to eliminate the statutory definition of hernia which describes it as ordinarily a physical weakness or ailment which develops gradually, and to eliminate the provision that hernia shall not be compensable unless conclusive proof is offered that it was immediately precipitated by such sudden effort or severe strain that (1) the descent of the hernia immediately followed, (2) there was actual pain in the hernial regions and (3) the manifestations were of such severity that they were immediately noted by the workman and communicated to the employer within forty-eight hours of the accident. H 632 proposes to create a board of drugless therapy education, examination and licensure, to consist of two chiropractors, two naturopaths and one neuropath and to regulate the practice of drugless therapy. Drugless therapy is to include chiropractic, naturopathy and neuropathy and is defined as the prevention of disease and treatment of the sick by any movements, adjustments and manipulations, performed by the hands or by any instruments or appliances and the use of any physical forces, such as air, light, water, heat and electricity, or any of their derivations foregoing therapeutic measures the use of nontoxic herbs and plants and their derivations dispensed, administered or prescribed, and minor surgery as a first aid and emergency measure and as practiced and taught in the various schools of drugless therapy. Any nontoxic herb or plant or its derivations which can be metabolized or has a food value is to be considered as nontoxic. Applicants for licenses after Sept. 1, 1931 must have in addition to their cult studies, a high school education and one year's college work in chemistry, physics and biology.

Philadelphia

Dr. Keen Celebrates Ninety-Fourth Birthday—Dr. William W. Keen celebrated his ninety-fourth birthday, January 19.

Dr. Keen received his M.D. degree from Jefferson Medical College in 1862. He was President of the American Medical Association, 1900-1901. During his career Dr. Keen has been a member of practically every important surgical organization and president of many. He has held many teaching positions and is the author of numerous publications.

Society News—Dr. Harry E. Knox, among others, addressed the Philadelphia Pediatric Society, February 10, on "Duodenal Veils in Infancy." Dr. Charles Francis Leake gave a card specimen of "Congenital Pulmonic Stenosis and Unusual Extracardiac Findings" at the February 12 meeting of the Pathological Society of Philadelphia. Dr. Valenz H. Parler, New York, lectured at the Woman's Medical College of Pennsylvania, February 10, on "Syphilis as a Public Health Problem." Dr. Ellen C. Potter, Trenton, N. J., will lecture April 10, on "The White House Conference of Child Health and Protection," and Dr. Mary R. Noble, Harrisburg, April 10, Pennsylvania Health Program for the Preschool Child.

RHODE ISLAND

Society News—The Providence Medical Association addressed, February 2, by Dr. John I. Pinkney on "Diagnosis of Early Pulmonary Tuberculosis in Childhood and Adolescence." Dr. Harry Lee Parnes discussed the condition in adults and Drs. Isaac Gerber and Emmanuel W. Benjamin, radiologic aspects. Dr. Vincent J. Ryan addressed the St. Joseph's Hospital Staff Association, Providence, February 12, on "Diagnosis and Treatment of Common Skin Lesions."

Bill Introduced—H 680 to amend the chiropractic practice act, proposes that any person at least 23 years of age, good moral character who shall before July 1, 1931, submit satisfactory evidence to the state board of chiropractic examiners that he practiced chiropractic in the state as his occupation for a period of seven years or more prior to July 1, 1927, may receive a certificate of exemption from examination and be recommended by the board of chiropractic examiners for a certificate of qualification to practice chiropractic.

SOUTH DAKOTA

Bills Introduced—H 239 proposes to prohibit physicians from charging more than 25 cents per mile for travel when engaged in professional services. H 254, to amend the chiropractic practice act, proposes (1) to define chiropractic as "the science of locating and correcting interferences with the transmission and expression, without the use of drugs or surgery, (2) to provide that chiropractors shall be subject to the same rules that govern physicians or healers of old schools as to births and deaths and the control of contagious diseases and (3) to grant them all the privileges accorded other physicians pertaining to the public health. H 178, to amend the nursing practice act, proposes to provide that a member of the board of nurse examiners may be connected with a training school for nurses.

TEXAS

Bill Introduced—H 453 proposes that the state board of health shall consist of nine members, six of whom shall be licensed physicians, one a dentist, one a pharmacist and one a sanitary engineer.

Society News—Dr. Witten B. Russ, San Antonio, elected president of the Texas Surgical Society at its fifteenth annual meeting in Greenville, February 23, succeeding Dr. Joseph D. Becton, Greenville. The 1932 meeting will be held in Houston. Dr. Sidney J. Wilson, among others, addressed a joint meeting of the Tarrant County Medical Society and Fort Worth Dental Society, January 6, on "Management of the Lower Lip Complicated by Mouth Infection."

UTAH

Bill Introduced—S 87, to amend the pharmacy practice act, proposes to raise the annual registration fees required of registered pharmacists to \$7 and of assistant pharmacists to \$3. Four dollars of each fee paid shall be for the use and benefit of the Utah Pharmaceutical Association and will entitle registrants to membership therein.

VERMONT

Bill Introduced—H 138 to amend the pharmacy practice act, proposes to raise from three to four years the period of apprenticeship or study required of applicants for licenses.

VIRGINIA

Personal—Dr Peter P. Crusey, Sedley, has resumed the duties of health officer of Southampton County, succeeding Dr Bathurst B. Bagby, who was recently promoted to director of the child health bureau of the state board of health, Richmond.

WASHINGTON

Bill Introduced—S 177 proposes to authorize the construction of an institution for the confinement, cure and rehabilitation of drug addicts. S 186, to amend the nursing practice act, proposes to provide (1) that all registered nurses shall reregister annually and pay an annual fee of \$1 (2) that all applicants for licenses as registered nurses must have had two years high school education, and (3) that only nurses who have had at least three years practical experience after graduation and who shall at the time of their appointments be actively engaged in the teaching or training of nurses shall be eligible for appointment as members of the examining committee.

WYOMING

Bills Introduced—S 78 proposes to increase from \$1 to \$2.50 the annual registration fee that licensed practitioners of medicine, surgery and osteopathy are required to pay to the board of medical examiners. S 60 proposes that the term of the board of examiners in optometry shall be four years.

GENERAL

Leprosy Association Formed—At the Leonard Wood Memorial Leprosy Conference held in Manila and Culion P. I., in January, the International Leprosy Association was formed with the following officers: Drs Victor G. Heiser, New York, president; Carlos Chagas, Brazil, and E. Muir, Calcutta, vice presidents; R. G. Cochrane, London, secretary; and Eli Edwin Brown, Manila, treasurer. Dr Herbert Windsor Wade, chief pathologist at the Culion leper colony and medical director of the Leonard Wood Memorial for the Eradication of Leprosy, will be editor of a quarterly journal of leprosy to be published by the association.

Annual Increase in Automobile Deaths—The National Safety Council reports that in thirty-three states and the District of Columbia, representing 75 per cent of the population 32,500 automobile deaths occurred during 1930, a 4 per cent increase over 1929. There was less than 1 per cent increase in motor vehicle registrations during the year. Ten states with strong drivers license laws showed an average decrease of 15 per cent. New Hampshire, Rhode Island, California, Connecticut, Maryland, Massachusetts, New Jersey, New York, Pennsylvania and Vermont. The states without standard drivers' license laws showed an increase of 83 per cent.

American Committee for Control of Rheumatism—The fourth meeting of the American Committee for the Control of Rheumatism was held, Dec 6, 1930, in Philadelphia. The need for state institutions for care of poor patients with chronic arthritis, the question of nomenclature for rheumatic disease and the value of sanatorium care and of climate were among the topics discussed. The committee plans to assemble information on the type of treatment offered by various prominent sanatoriums and the expense incident thereto and eventually to publish an annual review of progress in the study and treatment of rheumatic diseases. Members present were Drs Ralph Pemberton, Philadelphia, chairman; Robert B. Osgood, Boston; Joseph L. Miller, Chicago; Russell L. Cecil, New York; Russell L. Harden, Cleveland; and A. A. Fletcher, Toronto. Drs George R. Minot, Boston, and Philip S. Hench, Rochester, Minn., were elected to membership.

News of Epidemics—Schools were closed in Bowling Green, Ky., for two weeks beginning February 16 to combat an epidemic of scarlet fever. 500 cases having been reported in Warren County within a few weeks. Nine public schools and two private schools were affected. Epidemic meningitis is reported from Tennessee as follows: Memphis, twenty-one cases with thirteen deaths up to February 11; Knoxville, twelve cases with six deaths during January. Three cases occurred in Muhlenberg County, Ky., in January, with two deaths. Schools were closed in Marion, Ky., January 28 following the death of a high school student. New paper report smallpox at various points in the middle west. Thirty-five cases were reported, January 26 in Coal City, Ill., a town of about 1,000 persons. 250 school children were vaccinated at New Bremen, Ohio, after two became ill with the disease. In White Cloud, Mich., a town of about 600 persons, 101 cases were reported.

January 23, Grand Rapids, Mich., had nine cases. February 1, three cases at Pikeville, Ky., January 29, caused health officers to issue warning to citizens to be vaccinated.

American College of Physicians—The fifteenth annual clinical session of the American College of Physicians will be held in Baltimore, March 23-27, with an additional day in Washington, D. C. March 28. Symposia on gastro intestinal disease, heart disease, endocrine disorders, anemia and questions of public health, medical practice and medical economics are on the program in addition to general sessions devoted to varied topics. Special clinics and demonstrations at Johns Hopkins University School of Medicine, the University of Maryland School of Medicine and various Baltimore hospitals are to be given each afternoon of the meeting, from Tuesday to Friday, inclusive. Features of the Washington program are lectures at the U. S. Naval Medical School and at St. Elizabeth's Hospital, clinics and demonstrations at George Washington University School of Medicine, Georgetown University School of Medicine, Mt. Alto Hospital and Children's Hospital, demonstrations of arthritis and syphilis from the anthropological collections of the Smithsonian Institution and visits to Walter Reed General Hospital, the Army Medical Library and the Army Medical Museum. Among speakers who will present papers are Drs William S. Thayer, Warfield T. Longcope and Lewellys F. Barker, Baltimore; Henry A. Christian, George R. Minot and Frank H. Lihay, Boston; Ray M. Balveat, Oklahoma City; Cyrus C. Sturgis, Ann Arbor, Mich.; Gabriel Tucker, Philadelphia; George E. Tollansbee, Cleveland, and David P. Barr, St. Louis.

Medical Bills in Congress—S 255, the Jones maternity and infancy bill, amended to cover rural hygiene also, has passed the House. S 5959 has passed the House, authorizing the Secretary of the Treasury to purchase the state laboratory at Hamilton, Mont., constructed for the prevention, eradication and cure of spotted fever. S 6097 has passed the Senate, authorizing the construction and equipment of a hospital on Crow Indian Reservation, Montana. S 6171 has passed the House, regulating the prescribing and use of waters from the Hot Springs Reservation, Hot Springs, Ark. H. J. Res. 480 has passed the House, authorizing an appropriation to defray the expenses of participation by the United States in the Conference on the Limitation and Manufacture of Narcotic Drugs, to be held at Geneva, May 27. H. R. 6997 has been vetoed by the President, proposing to confer on certain persons who served in the quartermasters corps or under the jurisdiction of the Quartermaster General during the war with Spain the Philippine insurrection or the China relief expedition, the benefits of hospitalization and the privileges of the Soldiers' Home (H. Doc. 778). H. R. 12922 has passed the House providing for medals of honor and awards to government employees for distinguished service in science and for voluntary risk of life and health beyond the ordinary risks of duty. H. R. 17240, introduced by Representative Shott, West Virginia, and S 6227, introduced by Senator Copeland, New York, and Senator Hatfield, West Virginia, propose to provide for federal supervision and control, through federal subsidies of the activities of the several states in the physical rehabilitation, education, vocational guidance and vocational education of physically handicapped persons less than 21 years old.

FOREIGN

Medical Education in Russia—Medical education in the Union of Socialist Soviet Republics, which was reorganized in 1930, now has three divisions or faculties according to information furnished by the department of health, Moscow, through the American representative of the Russian Red Cross Societies. The faculties are (1) the curative prophylactic faculty, which is divided into surgical, therapeutic and stomatologic departments; (2) the sanitary prophylactic faculty, which is divided into epidemiologic, communal hygiene, nourishment and sanitary industrial department; and (3) the faculty for the protection of motherhood and childhood, which has two departments, one for mothers and infants, the other for children and adolescents. Except in the second division and the stomatologic department of the first medical instruction covers four years. After a year's internship graduate of the curative prophylactic faculty and of the faculty for the protection of motherhood and childhood have the right to practice medicine independently. Physicians who have received their medical training outside of Russia may practice only after they have completed a year of practical medical work in institutions controlled by the Commissariat of Health. Applicants must also pass examination on the principles of Soviet health protection.

Streptococcus Hemolyticus in Puerperal Fever and in the Throats of Attendants

An important report on the source of infection in puerperal fever, the result of researches by Dr John Smith of the City Laboratory, Aberdeen, has been issued by the Department of Health for Scotland. It is based on researches into the causation of 221 cases of puerperal fever and 25 cases of septic abortion occurring in Aberdeen over a period of eight years. Bacteriologic examinations were made of materials obtained from patients and from physicians, nurses and other attendants—in the last three classes chiefly nose and throat swabs. During this period all cases of puerperal fever admitted to the Aberdeen City Hospital for Infectious Diseases were submitted to routine bacteriologic investigation, with especial reference to the presence of *Streptococcus hemolyticus*. This organism was found associated with fatal cases of puerperal fever to an extent that left no doubt as to its importance. It was found in uterine cultures from 149 of the 221 cases, and in 120 cases it was present alone. It was found also in blood cultures in 22.9 per cent of the cases, while other organisms were found in only 3 per cent. Out of 46 fatal cases it was obtained from one or more sources in 43. In 25 cases of septic abortion it was obtained in pure culture from the uterus in 11 and in 3 other *Bacillus coli* was found. In 15 cases the only organism obtained from the uterus was *Streptococcus haemolyticus* and the source of infection was discovered in 12 of these. In 5 cases *B. coli* alone was obtained from uterine cultures and its source was discovered in each. In 12 cases the infecting strain of the streptococcus was found to originate in the throat or nose of the physician, nurse or student in attendance; in only one case was the infection of autogenous origin—from a septic focus in the patient's hand. In *B. coli* infections the organisms were derived from either the urinary tract or the intestine.

With regard to prophylaxis it is suggested that infection might be prevented if physicians, midwives and nurses used masks more frequently and adopted more careful antiseptic treatment of the hands. Further that in hospitals isolation of beds be introduced by means of glass screens interposed between the patients.

The Compulsory Insurance of Motorists and Hospital Staffs

In a previous letter it was reported that by the road traffic act motorists must insure against their liability for personal injuries to third parties and are liable to reimburse any hospital in which the injured person was treated up to a maximum of \$125. The Hospital Committee of the British Medical Association has therefore called the attention of the staffs of hospitals to the action to be taken in the new situation. The British Hospitals Association has been negotiating with insurance companies for a daily flat rate of payment where a claim under a third party policy has been established. The amount of the flat rate does not seem sufficient, but what the British Medical Association is mainly concerned with is that the interests of the medical staffs should not be overlooked. It suggests that the governing bodies of hospitals should be requested to make provision for the medical services rendered. The amount payable by the insurer is qualified by the definition that it shall be in terms of the daily cost per patient in hospital. This obviously provides for the cost of the medical attendance under special circumstances. It brings the service under the category for which the hospital policy of the association states that the cost of maintenance and medical treatment should be the sub-

ject of contribution to medical staff funds. The visiting medical staff should therefore insist that for all persons below the financial status of private patients an amount equal to one-fourth of the maintenance cost paid by the insurer to the hospital should be credited to the staff fund. When the injured third party is of the status of a private patient he should not be the subject of an application to the insurer but an account should be rendered to him as a private patient. The point is described by the association as an important one and it is declared to be desirable that a proper precedent should be established at the beginning.

International Congress of the History of Science

The second International Congress of the History of Science and Technology will be held in London at the Science Museum, South Kensington, from June 29 to July 3 under the presidency of the medical historian Dr Charles Singer. The committee originated with the Comité international d'histoire des sciences which was founded in 1928 and which meets annually in Paris and organizes a congress in the history of science every three years. In the coming congress this body, as well as the History of Science Society, New York, and the Newcomen Society for the Study of the History of Engineering will cooperate. The program will include visits to Kew Gardens (botanic), Docton House (Darwin's residence, now a museum of Darwin relics), Barber Surgeons' Hall and the Royal College of Physicians. Further particulars can be obtained from the secretary, Mr W. H. Dickinson, Science Museum, South Kensington, London, S. W. 7.

The Control of Proprietary Medicine

A bill emanating from the health advisory committee of the Socialist party, to be known as the proprietary medicines bill and intended to regulate the manufacture and sale of such preparations, is about to be brought forward. Its provisions are drastic and considerable opposition is already announced by manufacturers and pharmacists, but the provisions should with one exception receive approval from the medical profession. It is proposed to appoint a registrar to keep a book containing the names of the owners and all proprietary medicines and full particulars of their ingredients. Every such medicine must be registered and allotted a number, which must figure on any vessel or packet in which it is sold. The advertising of proprietary medicines is to be rigorously censored. No statement that a physician or dentist has recommended such a preparation may be published without his qualifications and address. It may be remarked that this practice is forbidden by the ethical rules of the medical profession. Quotations from medical journals must be accompanied by the name, date and page of the publication. It will be an offense for the vendor of a proprietary preparation to invite persons suffering from any ailment to correspond with him with a view to treatment. After six months from the passing of the act, no person will be permitted to sell any medicines or appliances purporting to cure or relieve deafness, or any other of ten ailments mentioned in the bill. The minister of health will be empowered to remove from the register any medicine that he considers likely to cause injury if used in accordance with its registered directions. One of the chief objects of the bill is the establishment of a new government department to act as an official censor of advertisements. The trade interests concerned will do everything in their power to oppose the bill, as they maintain that the compulsory publication of formulas would have the gravest effects on well known proprietary businesses, as well as injuring pharmacists by placing them entirely in physicians' hands.

Sir Andrew Balfour Is Dead

The death of Sir Andrew Balfour, director of the London School of Tropical Medicine, has removed a distinguished investigator and great administrator. Born in Edinburgh in 1873,

he graduated from the university in 1894 and joined his father, who was a physician, in practice. But his interest soon turned in the direction of hygiene and he proceeded to Cambridge, where he took the DPH and did research work on typhoid. In 1898 he took the M.D. of Edinburgh with a gold medal for a thesis on the toxicity of dyestuffs and river pollution. He served as a civil surgeon in the South African war in 1900-1901, and in the latter year came under the influence of Sir Patrick Manson. In 1902 he was appointed director of the Wellcome Tropical Research Laboratories at Khartoum and health officer of that town, from which he banished the mosquito and malaria. He made important contributions to protozoology—the spirchietosis of birds and of man—and discovered leishmanoid disease of the skin. He worked out the life history of spirochetes in the tick. He suggested a floating laboratory on the Nile, and a special vessel was constructed and presented to the Sudan government by Mr. Wellcome. He explored the upper reaches of the Nile, making further protozoological research. In 1913 he returned home and founded the Wellcome Bureau of Scientific Research in London. In that year he made a tour in the West Indies and South America and arrived at the conclusion that monkeys are the reservoir of yellow fever. This has since been confirmed. During the Great War he was a member of the medical advisory committee to the Mediterranean Expeditionary Force and subsequently its president. Later he was scientific adviser in the campaign in German East Africa and still later he was invited to Palestine to advise on the antimalaria measures. In 1921 and in 1923 he was sent by the colonial office to Mauritius and to Bermuda to report on the sanitary condition. In 1923 he was appointed director of the London School of Tropical Medicine, which was founded largely by the munificence of the Rockefeller Foundation. He supervised every detail in the construction of this school, which was an advance on anything previously in existence in this country. In 1926 he delivered the opening address at the Johns Hopkins School of Hygiene. From 1925 to 1927 he was president of the Royal Society of Tropical Medicine. In 1930 his health broke down from a career of overwork, of which his untimely death is the result. In addition to his medical works, such as "Public Health and Preventive Medicine," "Memoranda of Medical Diseases in Tropical and Subtropical Areas" and "Health Problems of the British Empire," he wrote fiction. One book, *The Golden Kingdom*, was based on the tragedy of trypanosomiasis in Africa. He was created C.M.G. in 1912, C.B. in 1918 and K.C.M.G. in 1930. He was made D.Sc. and LL.D. of Edinburgh and LL.D. of the Johns Hopkins and Rochester universities. He leaves a widow and two sons.

Yellow Fever in Laboratory Workers in London

Three cases of contraction of yellow fever in the course of laboratory work have been observed in London. An assistant working in the Wellcome Bureau of Scientific Research with a Brazilian strain of the virus maintained in monkeys became infected. He was admitted to the Hospital for Tropical Diseases and treated with immune serum. The case ran a typical course of a moderate infection and terminated in recovery. The second patient examined the blood of the first and ten days later was taken ill. Blood taken from him eighty-nine hours after the onset produced fatal yellow fever in a monkey. After an illness of a month he recovered. A laboratory worker collected blood from this patient and performed a blood count on it. After an incubation period of ten days he developed a severe attack of yellow fever, and in spite of treatment with convalescent serum he died.

Dr. G. Carmichael Low and Dr. A. H. Farley, who have recorded these cases in the *British Medical Journal*, point out that the second and third cases establish the important fact that the virus of yellow fever can penetrate the intact skin of the hand. These cases show the great danger of taking blood

at least during the first four days of fever. In the laboratory of the Hospital for Tropical Diseases, antiseptic lotions were used for the hands, all utensils that came in contact with infective blood were sterilized, but gloves were not worn. This appears to be the only effective measure for preventing infection, for those who wore them in collecting and handling infective blood did not acquire the disease. In monkeys, 1 cc. of blood on the first day of fever contains from one to ten million certainly fatal doses. Microscopic quantities of blood will therefore probably infect. The excreta of yellow fever patients are generally regarded as noninfective and also the organs at necropsy, owing to disappearance of the virus at the time of death. But this should not be too lightly assumed, and precautions should be taken in cases of death before the fifth day of the disease.

Psychopathic Hospitals in the French Colonies

A comprehensive article on the psychopathic hospitals of the French colonies has just been published. There are not so many of these but they are nearly all modern and remarkably well organized. They were built, in the first place, chiefly for the care of Europeans. The natives have a different idea of insanity from ours. The mental patient, as they view him, is a being inspired by some spirit and hence commands respect. But, with the increase in the number of native physicians and nurses, these ideas are becoming modified, and all the present hospitals are beginning to admit native mental patients, so that it has become necessary to provide several different sections, in order to separate the races and the sexes. The spread of alcoholism has contributed a great deal to the increase in the number of mental cases, both among the Europeans and among the natives. The most important psychopathic hospital in the French colonies is located at Bien Hoa in Cochinchina. It is surrounded by a tract of 17 hectares (42 acres) lying 33 kilometers from Saigon. It is electrically equipped and has pure water and swimming pools. A large portion of the tract is under cultivation and there are a number of workshops. The field work and the shop work furnish employment to the inmates, whereby the expenses of the institution are considerably reduced. During the period 1919-1928, 1,009 patients were admitted to the institution at Bien Hoa, of which number 16 were French, 13metis (persons of mixed blood), 827 Annamese, 66 Cambodians, 22 Tonkinese, 2 Laos, 56 Chinese, 2 Hindus and 2 Malays. Most of the Chinese, as soon as the first symptoms appear, are sent to their home country. Mental disease was most prevalent in the 21-45 age groups, there having been 608 men as compared with 401 women. The incidence was much greater among unmarried than among married men. Another similar hospital will be opened soon at Tonkin which is rapidly increasing in population and which is located a long distance from Saigon. A large hospital for mental patients has likewise been erected in Madagascar in the province of Ambolo. It is 18 kilometers from Tananarive. Its grounds comprise 4 hectares (10 acres) with eighteen pavilions, one of which is reserved for European men, another for European women, two pavilions are for native women, nine for native men, one pavilion with nine rooms is an isolation ward for hyperventilable cases, in addition to which there are pavilions for hydrotherapy, for the housing of the personnel, store rooms and kitchen. There is also an annex of the hospital consisting of a pavilion located on the terrain of the former Ambolo Leprosarium which is reserved for convalescents. Neither French West Africa nor French Equatorial Africa has as yet a psychopathic hospital but in his contemplated loan Cardon, the governor general has figured 3,000,000 francs (\$120,000) for the erection of a psychopathic hospital which will probably be located in

the Senegal region. Among the older colonies, Reunion Island and Guadeloupe each possesses a psychopathic hospital. The hospital at Saint-Pierre, Martinique Island, was destroyed in the Mont Pelée eruption in 1902. The hospital on Reunion Island is installed in a former colonial hospital at Saint-Paul. It comprises a section for men, a section for women and several pavilions to which pry patients or mild cases are admitted. The psychopathic hospital of Guadeloupe is located at Saint Claude. It admits mental patients from Guadeloupe, patients from Martinique since the destruction of the Saint-Pierre hospital, and a few patients from Haiti.

Physician and Artist

In a recent number of the *Deutsche medizinische Hochschrift*, Dr. Edwin Redslob, federal art commissioner, attached to the federal ministry of the interior, discusses the profound relations that exist between physician and artist. He describes Ernst Ludwig Kirchner as an artist who portrays, by means of many different modern devices, the secret of the eye that penetrates one's inmost soul and the mysteries of art by subtle inventions that cannot be learned in the art schools. In illustration of his argument, he tells this story. In 1915, when Kirchner, severely ill and scarcely able to move, reached the sanatorium in Kreuzlingen, he lay on a cot for examination while a number of physicians stood about him. Through a gap in the group of physicians standing about, the artist suddenly caught sight of a brilliantly plumaged parrot, and now what happened can best be understood by recalling Goethe's 'The Sesenheim Ride.' The artist was given, for a moment, the gift of second sight, enabling him distinctly to view himself lying there on the cot. The creative power within him had been touched and the artist forgot that he himself was the patient. He was conscious of only one thing: this picture with its vivid contrast between intense anxiety and the brilliant plumage of the parrot, a picture that he painted later. Such a situation shows how a work of art takes shape in the artist's mind, how, often, a single moment in which the artist is transported from the realm of the commonplace to the realm of the supersensuous furnishes him his first vivid conception. Such a situation is of interest to the modern physician, as it is especially instructive. The physician finds here the crossing to a knowledge of the psyche, the connection with the realm of the pathologic subconscious. And if, then, in persons whose minds have become apparently permanently enveloped by an impenetrable cloud he is able to discover the fundamental *motif* that a vivid impression suddenly dug in the patient's brain, he will find if it is in any wise possible, also the key to the treatment, and often the way and the means for the cure of the patient. It may be added that artistic intuition is not an uncommon manifestation in the physician.

Death of the Human Heart

Addressing the Berliner Medizinische Gesellschaft recently, Professor Hoeslin presented a number of electrocardiographic curves that he recorded in man during the last moments of life. It may be observed that the heart continues to execute contractions for a period after all life appears to be extinguished, that is, after respiration has ceased and pulse and heart tones can no longer be perceived. For several minutes—in some cases for as much as half an hour or longer—contractions occur, to be sure, gradually getting weaker and noted at increasingly long intervals. Sometimes, just before the final standstill, a period of increased stimulation sets in: that is, there develops for a short period a rapid beating, before a complete cessation occurs. In reality, however, not all life has left the heart even now, for certain elements may execute contractions yet and may respond

to stimuli. The elements in question are muscle fibers that run through the so-called tendon threads of the heart. In certain patients who previously were apparently perfectly well and at under some emotional shock suddenly collapse and are dead, Hoeslin succeeded in a few cases in recording with the electrocardiograph the condition of the heart at this moment. The cardiograph record revealed that the heart executes no further regular contractions but that its musculature has entered a condition characterized by fibrillation and irregular writhing movements, from which it does not recover. The movements gradually grow weaker, and after a short period (at the most six or seven minutes, according to the record) the permanent standstill occurs. Through intracardial injection of cardiac remedies (camphor, strophanthine, epinephrine), strong mechanical agitation or the application of induction currents, attempts have been made to restore regular beating of the heart. In no carefully recorded case has that been accomplished—at least, not after the aforementioned writhing of the heart had certainly occurred. It is more likely to be accomplished immediately after a sudden standstill of short duration. The cause of sudden death of heart origin may lie in a failure of the heart action with subsequent filling with blood through increase of the arterial resistance. No doubt the nerves supplying the heart play a part, and may be, in fact, in some instances, the sole cause. In analogy with the animal experiment, possibly here is an explanation for the sudden deaths that, without question, are caused solely by fibrillation, and in which an apparently healthy heart (and perhaps occasionally even an actually healthy heart) may suddenly enter a state of fibrillation that ends in death. In rare cases, it is a result of exertions or also through nervous influence. A great burden may be thrown on the heart muscle, whose functioning was previously impaired, or on the aorta and the blood flows through a tear in the wall into the pericardium or into the thoracic cavity, which naturally results in immediate death due to mechanical compression. It is to be hoped that, at least in isolated cases, endeavors to convert the standstill or the tortive movements into normal and, above all, continuous contractions may be crowned with success. That will be possible only in the event that the heart muscle is not too severely damaged and still has a reasonable amount of vitality.

The Number of Students

The total number of students matriculated at the universities of the German *reich* was, in the summer semester of 1930, 132,090, as compared with 122,391 in the winter semester of 1929, 1930 and 123,700 in the summer semester of 1929. Of the students in the summer semester of 1930, 95 per cent were German citizens and 5 per cent were foreigners. The number of freshmen entering during the summer semester 1930, which is evidence of the present eagerness to pursue higher studies, was 24,160, exclusive of foreigners. Of this number, 22 per cent were women (in the summer semester of 1929, 19 per cent). The proportion of men students, on the other hand, shows a decline. Taking the attendance at all the universities, the increase since 1925 has been 49 per cent. The University of Berlin still has the largest attendance (nearly 20,000), Munich has the second largest number (more than 12,000). The women students, as in the past, favored these subjects: medicine, modern languages, Germanic philology, pedagogy for public school teachers, mathematics, jurisprudence, political science, biology and the natural sciences.

Death of Prof. Leopold Kuttner

Jan 22, 1931, Prof. Leopold Kuttner succumbed to a protracted illness, at the age of 65. His passing signifies a great loss to medicine. He was regarded as an eminent internist. His calmness of manner, his attitude of assurance and, more particularly, his careful and devoted way of dealing with patients caused him to be for decades one of the most popular consultants

In the position of medical director of the Rudolf-Virchow-Krankenhaus in Berlin, which post he held from 1910 on, he proved his peculiar ability as a clinical leader. His voice was heard on all important questions affecting the hospital system of Berlin. Under the influence of Ewald, the director of the Berlin Augusta-Hospital, he devoted himself more particularly to diseases of the stomach, and in this field he soon gained a far-reaching reputation. In addition to an extensive practice as consultant and largely attended courses for students and physicians, he developed a comprehensive scientific activity. In collaboration with Lindner, he prepared a work on the surgery of the stomach. He is the author of excellent descriptions of appendicitis, gallbladder disease, cancer of the intestine and gastric ulcer. The present knowledge of the significance of occult hemorrhages is intimately associated with his name.

Joint Session of Pediatric Societies

At a joint session of the Societe belge de pediatrie and the pediatric societies of Strasbourg and Geneva, among the more important communications, were the following:

THE PROPHYLAXIS OF TUBERCULOSIS IN CHILDREN

Dr Delcourt, who discussed the various modes of prophylaxis of tuberculosis in children, said there is general agreement that 90 per cent of the persons who become infected are infected with tuberculosis by the time they are 15 years old. Hence, it is before the age of 15 that prophylaxis must be applied. The crusade against tuberculosis should be chiefly prophylactic, for a disease that is everywhere and that causes 20,000 deaths annually cannot be routed by the application, in a few thousand cases, of pneumothorax, costectomy, phrenectomy and pneumolysis. The role of the sanatoriums is important. But if their number were increased a hundred fold they would be still insufficient. Devoted physicians make praiseworthy efforts to help patients and sometimes succeed in curing them and turning them back to society. It is the task of the physician to do everything in his power and to inspire the soul of the patient with hope. But it is not by a direct attack on tuberculosis in process of evolution, after it has caused often irreparable damage, that tuberculosis is to be conquered. A prophylaxis well understood will aid, and such prophylaxis must be general and complete.

Among the available means are the vacation colonies and the fresh air resorts. An indispensable condition for the admission of children to such treatment is a complete examination which should be made by a pediatrician familiar with tuberculous lesions in the child. But, alas! all too often frankly tuberculous children are sent to colonies along with weakly children, where they become sources of infection. Children who present lesions that are detectable by a careful examination require a special treatment, an appropriate diet and a management that they can not find other than in a sanatorium specially organized for their care.

PERTUSSIS

According to the classic doctrine pertussis is an infectious disease characterized by a slight catarrh of the upper air passages. Drs Pospischill and Fevter of Vienna were able to show, by means of histologic examinations in 100 cases characterized by lesions of the lungs in pertussis the nucleus of which was a peribronchovascular inflammation. Dr Corcu of Strasbourg by means of the radiologic examination was able to confirm the observations of Pospischill. He found radiologic evidence of constant changes characterized by tracheobronchial adenopathy and shadows that descend along the hilum toward the peribronchovascular space, producing in grave cases a triangular image with the diaphragm, producing in the base on the dia-

Pertussis is certainly not an insignificant catarrh of the air passages. It is associated with typical lesions that are revealed radiologically and that persist a long time after the paroxysms of coughing have ceased.

Supervision of Pharmaceutic Products

In his presidential address before the Congress of Pharmacy, Professor Schoofs of Liege called attention to the control of pharmaceutic specialties. The law in Belgium requires the formula of a pharmaceutic product to be stated on the label, but what guarantee has the purchaser that its composition actually corresponds to the formula given? Often, there is deception in the quality of the product sold. Physicians receive daily, in great number and free of charge, samples of these specialized products. Some contain active principles, among which one may mention atropine, hyoscyamine, sparteine, morphine, narcotine, codeine and ethylmorphine hydrochloride. Are these principles actually present? If so, in what doses? What is their degree of purity? Physicians prescribe readily these specialties, without other guarantee than the vague indications contained in a prospectus. The public, incompetent to judge but captivated by the outward appearance of the package and by deceptive advertising purchases these products at a high price, though often ineffective and sometimes even contraindicated, without consulting a physician, and thus all this damages the public health. A strict and effective control is needed. The pharmacists should examine these specialties, which, like the other preparations of their laboratory, are controlled by the inspection service.

Regulations Concerning the Title of Specialist

As a supplement to the resolution passed by the Congress of Occupational Medicine, the Federation medicale belge commissioned Professor Coppez to prepare a plan for the regulation and control of the title of specialist in the various branches of medicine. After a study of the question, Coppez has published his conclusions. He considers that 1 Under present social conditions a system of certification authorizing a physician to assume the title of specialist in a given specialty is indispensable. 2 The specialties in which such certification would be granted would be those recognized by the law pertaining to higher instruction, dated May 21, 1929: surgery, pediatrics, ophthalmology, otorhinolaryngology, dermatosyphilology, psychiatry, gynecology, urology, physical therapy. (To these might be added the specialties of internal medicine, diseases of the nervous system, and of the respiratory, digestive and cardiorenal apparatus.) 3 In order to obtain the title of specialist in a given branch the candidate should take in a recognized clinic a special course of training, the duration of which would naturally vary with the nature of the specialty. 4 An examination controlling such supplementary studies in the field of a given specialty is not desirable. 5 There should be created through the cooperation of the government and the Federation medicale belge commissions on specialists (one for each specialty) composed of university professors, heads of hospital services and practitioners who have acquired unquestionable skill in their specialty.

The commission for each specialty would prepare a list of hospital services and the like in which candidates for certification in that specialty would be allowed to take a special course of training in the capacity of assistants; it would confirm the certificates issued by the hospitals or other institutions in which such special course was taken, it would render a decision in any special matter that might arise and would provide an official list of those entitled to practice a specialty which would be given for the inspection of the public authorities and medicosocial bodies. 6 Only certified specialists would be permitted to announce themselves as such on their door plate and their prescription blank. They alone would be entitled to membership in scientific or professional societies for the promotion of their specialty.

Health Conditions in the Pacific Islands

Throughout the whole of Melanesia there are three almost universally prevalent diseases, filariasis, frambesia (yaws) and hookworm infestation. Malaria is present in northern Melanesia (Papua, New Guinea and Solomon Islands) but is absent in the southern half, which includes Fiji, New Caledonia and the New Hebrides. Leprosy is prevalent to an enormous extent in southern Melanesia. Tuberculosis and other respiratory infections are relatively widespread in the neighborhood of white settlements. Bacillary dysentery is mildly endemic in most parts. Gonorrhea is prevalent in areas where laborers have returned from indenture.

The popular idea that the reaction of the native races to European contact results in a process of depopulation is considered by the mission to require qualification. The average infant mortality rate in malarious districts is 176.24 per thousand births during the first year of life, while in malarious free islands the rate is 158.3. The rate is tending to increase.

The diet of the Melanesian in his own village is bulky, not nutritious, difficult to digest, deficient in fat and in protein and often poor in vitamins A and C. The great majority of the natives live on a borderline diet or alternate between periods of plenty and periods of starvation.

It is concluded that a study of the causes of depopulation with correction of such as can be corrected, the institution of measures for the preservation of infant life by antenatal education of mothers and by the reduction of infantile mortality, the rapid dissemination of medical aid by routine medication and sanitation and the furthering of research and of native medical education will provide means for the control of health in Melanesia.

Such is a sketch of the report of the mission entrusted with a survey of health conditions in the Pacific Islands, published by the League of Nations Health Organization. The commissioners were Dr. P. Hermant and Dr. R. W. Cilento. The former is a Frenchman and the latter an Australian, thus selected on account of France and Australia being the chief nations represented in Melanesia.

Asiatic and Indian immigration was found to have a considerable influence on the disease picture. The distribution of amebic dysentery appears to coincide almost exactly with the distribution of Asiatic population. The same holds true with regard to the distribution of ancylostomiasis, ascariasis and probably other parasitic diseases. Fiji has a large population of Indians, almost equivalent in numbers to the native Fijian population. The Indians have certain definite disease characteristics which have tended to obscure and to modify the disease picture of the indigenous Melanesian. In New Caledonia a similar condition exists, but here it tends to become even more pronounced because, if the Loyalty Islands which have no Asiatic immigration, are excluded the indigenous population in that locality amounts to only 17,000. During the last five years Indo-Chinese labor has been introduced into the New Hebrides. A total of some 5,000 persons has been introduced and this number is increasing. Problems similar to those existing in New Caledonia and Fiji will presumably arise. In Fiji, where the Indian population is now fixed, immigration is small and indenture has ceased the process of modification may be said to be relatively at an end.

SPECIFIC DISEASES

Frambesia is almost universal in Melanesia in the coastal areas. The disease responds so readily to organic arsenic preparations that the use of these drugs has become an important factor in extending the influence of medicine to hostile tribes. The absence of syphilis among natives and the relationship

between frambesia and syphilis are important considerations in southern Melanesia on account of Asiatic immigration. This question is not so important in northern Melanesia, where there is no record of the occurrence of syphilis in a native.

The indigenous hookworm throughout the whole of Melanesia is *Necator americanus*. It is extremely widespread but appears to be of little significance or importance in actual hospital statistics. It probably acts by reducing the resistance to other diseases. In most areas it is possible to cope with the situation by occasional mass treatment. These conditions do not obtain when the causative organism is *Ancylostoma duodenale*. This organism is associated with Asiatic immigration. Its virulence is much more pronounced than that of *Necator*, it is much harder to expel, and it is not affected to the same degree as *Necator* by carbon tetrachloride. It is thought that the ancylostome is a factor of importance in certain European communities throughout the archipelago.

Filariasis is almost universal in Melanesia. It is a potent factor in economic loss. Elephantiasis, apart from the disfigurement that it causes, cripples a definite proportion of the natives and may have a minor effect on population. Among the manifestations of filariasis are abscesses of muscle, these may be either filarial or nonfilarial in type. It is only recently that attention has been devoted to myositis in the Pacific as a specific entity related to filariasis. The proportion of persons affected varies greatly from place to place, from 100 per cent to complete absence. Sayers has found areas which are free from filariasis or elephantiasis and it is noticed that in such areas myositis occurs as commonly and occasionally more commonly than elsewhere where filariasis is rife. It is suggested that this demands investigation. Other problems requiring investigation are the question of periodicity and that of the vector of the disease, which has been actually established only in some few localities.

Malaria is present in northern but absent in southern Melanesia. The possibility of its introduction into Fiji or New Caledonia calls for serious consideration. The factors that prevent the introduction of the disease have not been definitely determined. It is considered that malaria does not exist in either territory because anophelines have not been found. There is no adequate evidence of the nonexistence of anophelines other than the accepted fact of the absence of malaria and the fact that anophelines have not been discovered by any entomologic collector. It is considered most desirable that there should be a comprehensive survey of the whole of Melanesia with regard to the question of the vectors of both filariasis and malaria. Stress is also laid on the necessity for an examination of the whole of the literature dealing with the most important features of coordinated research that could be instituted. Since most of the administrations have neither the man nor the money for such an undertaking, it would be necessary for the scheme to be financed from outside.

Syphilis is virtually nonexistent except as a possibility of the future. On the other hand, gonorrhea is fairly common. The type of the infection is unusual in that it produces few complications and the question has been raised in some localities as to whether the disease is actually gonorrhea or As intercourse between the tribal groups becomes more frequent and intermarriage more usual, it is probable that the disease will progress.

Bacillary dysentery is not the scourge that it formerly was and the provision of adequate serum treatment aborts it with dramatic suddenness. Amebic dysentery, on the other hand, demands careful consideration. Since this disease is one of local routine, it is not considered that proper and suitable coordinated research could be recommended.

Tuberculosis is regarded as the most important feature in the problem of depopulation in certain of the administrations in Melanesia. The conclusions of the mission confirm the view expressed by Buxton in his report on the New Hebrides.

that there is some factor which outruns European penetration or civilization and which has a deleterious effect on the natives and that this factor is probably tuberculosis. As a result of the examination of the bodies of native laborers dying at Rabaul, it has been found that 24 per cent of all indentured laborers die of tuberculosis and that pneumococcal infection accounts for an equivalent number. In other words, half the total deaths of laborers are due to pneumonia or tuberculosis. The native develops but little resistance to diseases of this nature. It is suggested that he has not acquired the partial immunity found among European peoples. At the same time there is another factor to be considered—the food supply. The surprisingly good effects in certain localities of cod liver oil treatment and the important observations in relation to dietetic deficiencies indicate that in this field there may be an important factor in regard to survival.

Typhoid has not been seen in the British Solomon Islands Protectorate. It is extremely rare in Papua. It is becoming increasingly frequent in Rabaul and is engaging the serious attention of the administration. In Fiji and in New Caledonia it is a matter of the greatest importance.

Measles is said to have destroyed one third of the population of Fiji in 1874-1875 and in a second epidemic years later destroyed thousands of people, but it occurs at present without any virulent symptoms. The experience of Fiji has not been paralleled in any other part of the Pacific under review. In general, it is concluded that measles need no longer be feared. Diphtheria is beginning to assume the characters seen in civilized countries. Scarlet fever does not seem to occur.

THE INFLUENCE OF WHITE COLONIZATION

The mission did not express any definite opinions as to the manner in which white colonization affected the native population. The problem resolves itself into the adjustment of the native population to the 'civilized' environment. There are three stages of reaction to European contact. With the arrival of the white man there is an enormous initial decline of many native stocks. Secondly, there occurs a period which is relatively stationary. During this period the native struggles to adjust himself to his altered environment and his survival picture fluctuates irregularly toward an unstable equilibrium which is readily upset by any minor factor. This partial equilibrium is so delicate that pronounced effects may be produced on it by circumstances that would appear otherwise to have only a casual significance. Students of the depopulation of Melanesia have suggested numerous causes. Actual destruction of native life by violence may be disregarded. Over recruitment is now prohibited by rules and regulations. The wearing of clothes is found to have no significance one way or the other when observations have been made among populations, clothed and unclothed. Certain factors however are regarded as of definite importance. These factors are not confined to Melanesia but are universal in their application and would have an effect for depopulation on the members of any race. Whether their significance is sufficient to explain the present problem in Melanesia must be a matter for future investigation. These factors are the heavy infant mortality rate, the mortality rate at all ages from preventable disease and the fact that the great majority of natives alternate between periods of plenty and periods of actual starvation. The problem of depopulation in most instances may be solved by assisting the natives through the period of unstable equilibrium into the safeguards that insure the continuance of ordinary civilized races and particularly from a medical view by adjusting sociological questions.

MEDICAL EDUCATION AMONG NATIVES

Medical problems of Melanesia are complicated by the low state of civilization, the belief in magic and the scattered nature and the smallness of the native communities. It was

suggested long ago that it would ultimately be necessary to train and employ natives in a medical service. Experiments have been made in two directions. As early as 1885 the government of Fiji invited the chiefs to send eight or ten young men of approved intelligence and character with a view to their being given a course of instruction in the rudiments of human anatomy and physiology, medicine and surgery, together with the ultimate status after three years' service of native medical practitioner. In 1906 or 1907 a class of native women for training as midwives was instituted at a hospital under the supervision of a matron, the course being limited to six months or to assistance at a set number of deliveries. These schemes were continued for a number of years, but after a survey by Dr V G Heiser of the International Health Board of the Rockefeller Foundation, in 1916, it was thought that something more was needed if the native medical practitioner was to be a power in the country. Ultimately a central medical school was established at Fiji for the training of forty students. The Rockefeller Foundation agreed to contribute to this a diminishing proportion of the total expenditure for four years. After this period the responsibility for the continuance of the scheme was to fall upon the high commissioner for the Western Pacific. Among the students were to be twenty drawn from Fiji, four from the British Solomons and several Indian students. The administration of the territory of New Guinea has realized the difficulties of the former scheme and it has begun at the other end of the scale. An intelligent native is withdrawn from every village under control and is trained for three months at the nearest European and native hospitals in the simple technique of the commoner native diseases. He returns to his village free from head tax, accepted as a member of the local native administration and with a title of 'doctor boy' or 'medical tultul'. Every year he returns to the hospital for a recapitulatory course. The work done by these boys is surprisingly in excess of the slight training they receive, but their value lies not so much in this as in the fact that they represent an intelligent service of a wide-spread nature and they are an educational factor that makes civilized medicine a desirable commonplace to the natives of the village. Those now employed in the mandated territory number 2098 and some of them have a creditable length of service. It is thought that in twenty years it may be possible with the betterment of education and of living standards to train native medical practitioners to fill junior posts in the medical service for natives.

INFANT AND MATERNAL WELFARE

One of the largest factors in the diminution of native population is the great mortality that occurs during the first five years of life. In this matter it is the ignorance of the village mother that is of primary importance. The question of abortion and infanticide is of importance. Where polygamy was the rule certain anti-social practices have grown up since the substitution of monogamy as a result of the influence of missionaries. In some tribes a woman is deserted by her husband if she becomes pregnant because there is no other woman to carry out her domestic and agricultural duties. For the same reason a woman sometimes continues to work until she is in an advanced stage of pregnancy. Abortion is frequent from this cause and no premature infant survives among native people. In regard to infanticide Melanesians have for generations terminated pregnancy by the use of man plants most of which owe any potency they possess to the presence of tannic acid or by mechanical means such as the prolonged pressure of the pregnant uterus through the abdominal wall. It is estimated that eight or nine mothers died in every thousand births in these areas this figure was as high as sixty-five. Infants who are born are successfully born the hope to raise many children such as mulla feeding early weaning and perfect child rearing.

The training of native nurses and midwives has usually been attended with little success, owing partly to the type of women undertaking the work and partly to the extremely low status of women in most Mohammedan communities. A description is given of the work of committees of native women formed in the villages under the protection of the chiefs and at the urging of the government. This consists of a kind of public infant welfare clinic. It is founded on a knowledge of the psychology of the native and is described as already becoming extremely valuable. The activities for the care of pregnant women, for the feeding of infants and for the safeguarding of children up to the age of puberty represent the most direct attack on the problem of depopulation observed by the mission.

TURKEY

(From Our Regular Correspondent)

Ankara, Jan 8, 1931

The Opium Question

In regard to publications made recently by some foreign papers, especially Egyptian, concerning the illicit introduction of opium from Turkey, the Turkish official press replies. Because the object of the international opium convention of the League of Nations in 1921 was the ultimate restriction of opium cultivation, and considering from the economic point of view that the cultivation of opium is of importance to Turkey, we did not accept the League's invitation at the time. Besides, there are in Istanbul three commercial laboratories concerned with the manufacture of opium preparations and derivatives for medicinal use. That makes Turkey not only an exporter of opium but also a manufacturer of opium preparations and derivatives. On the other hand, Turkey, being through no convention under any obligation has never lost sight of the humanitarian point of view and under no circumstances has this point of view been departed from. With the humanitarian object in view the law concerning the manufacture of drugs and narcotics imposes certain conditions on laboratories manufacturing narcotic preparations and it controls the dispensing of such preparations within the country, controls the export of such preparations and has made prohibitive and punishable their illicit export. Besides at the time those laboratories export preparations of opium and its derivatives the consulates of the respective countries in Turkey are at once informed as to the amount and kind of the preparations about to be exported. Thus an opportunity is given for precaution to be taken by those countries. It is not right to confuse the good intentions Turkey has in regard to the use of opium for nonmedicinal purposes if despite all vigilance smuggling does occur. Turkey has been represented at all later opium conferences, at the preliminary conference in London in 1930, and is again to be represented at the Geneva conference in January, 1931. It should be added that Turkey does not shrink from becoming a member of the opium convention. But if the object of the opium convention or of countries that do not cultivate opium, or of some European countries that cultivate only a little, is to assume the monopoly of the manufacture of opium preparations and derivatives, this would be regarded as an injustice. The right Turkey has as an opium cultivating country should be recognized and a chance be provided for the sale of its opium preparations and derivatives in proportion to the amount produced. When this is realized a great step will have been made toward the international solution of the opium question.

The summary of a leading article on the opium question of another official daily reads thus: Turkey is ready to enter the international opium conference, to put under control the cultivation of opium and the manufacture of opium derivatives, and to permit export only by licenses. We can even go further and establish a government monopoly. Lastly we are ready to cooperate in all respects so that the humanitarian object may

be realized, but on condition that Turkey, whose cultivation of opium is extensive, be given a share on the world market in proportion to its extensive opium cultivation and to the manufacture of its numerous derivatives, which is important from the industrial point of view.

Prohibition on Importation of Gluside

The production of sugar in Turkey is not yet sufficiently developed to supply the country's demand, so imported sugar still plays an important part. Sugar costs twice as much here as in the United States. The Turkish diet is largely carbohydrate, and there are a great number of dishes, distinctly Turkish, in which the sugar content is high, from about 60 to more than 90 per cent. Among these are baklava, Turkish delight and helva, a preparation of sugar and sesame oil often with the addition of various nutmeats. As the latter does not require any additional preparation, it is a great favorite among the poor workmen, especially in winter.

The importation of gluside has in late years considerably increased but it is now being strictly prohibited. Only by special permission, which may be granted solely by the ministry of health is gluside necessary for medical treatment and other scientific purposes permitted to pass the customs. In order to import gluside one must apply to the ministry of health stating with what firm he intends to place the order and the amount he intends to import. The order may be made only after permission has been duly procured. Unless permission has been issued by the ministry of health, gluside will not be allowed to pass the customs. Gluside is sold at pharmacies only by prescription. Pharmaceutical houses are to sell wholesale only to institutions, pharmacies and manufacturers of proprietary medicines. Pharmacies, pharmaceutical houses and manufacturers of proprietary medicines are to keep a special book in which to enter the amount of gluside bought and from whom, the amount sold or otherwise disposed of, the date on which gluside was bought and sold, to whom, and with which prescription number. Pharmaceutical houses are to procure from their customers a signed statement as to the gluside sold them, which they are to preserve. If gluside is found in quarters of unauthorized persons these persons will be punished according to law, and the gluside confiscated.

Licenses Required for Milk Plants

Milk in Turkey is still being sold without being pasteurized. In some large cities, the child welfare societies have acquired small pasteurization plants where in limited quantities milk is dispensed for infants and preschool children. The milk of cows and buffaloes, which may be had all the year round, is being used for general consumption, in spring and summer the supply of sheep's and goat's milk is plentiful and at that time is often preferred for household use along with yoghurt (*Bacillus bulgaricus*), which may be made from all kinds of milk but is best prepared from the milk of sheep.

In cities the milk supplies are under the supervision of the municipal health departments. The specific gravity is being ascertained regularly, bacteriologic counts and tests for fat are made only on indication. Without exception all milk for consumption is being boiled in the homes. The tuberculin test for cows is not everywhere required. Recently the veterinary department of the Istanbul municipality has made an investigation as to the prevalence of tuberculosis among cows, out of 9,756 cows vaccinated, 632, or 6.4 per cent, had positive reactions. With the enforcement of the new public health law all kinds of milk plants, dairies or individuals selling milk are obliged to procure a license. Plants, dairies, means of milk transportation, milk selling stations and utensils are subject to inspection and control by the municipal health inspector. The different kinds of milk, the qualities of milk products, the condition of milk production plants, selling places and utensils are to be specified by the ministry of health in cooperation with

the ministry of national economy and to be issued as a municipal order. Licenses may be revoked if conditions do not comply with the minimum standard, or if utensils are insufficient.

The International Congress of Catholic Physicians

On the occasion of the Saint Emericus jubilee, the Catholic physicians of the world held an international congress in Budapest, last month. Professor Nekam, who presided, emphasized the fact that ethical problems should be discussed by authorities who stand also on positive religious ground.

Professor Pasteau of Paris, who spoke on Catholic physicians and the sex education of the nation, said that it is the duty of physicians, chemists, nurses and midwives in order to save the family and the community, to carry religion into the life of individuals. Marriage is not a union of interests and pleasure but the first act leading women to maternity. Intentional childless marriages, or marriages in which the number of children is artificially regulated, sin against nature. Physicians should explain moral hygiene from a medical point of view to parents, because it pertains to their sphere of action.

Pasteau, as president of the Saint Damian Catholic medical society, founded in 1884, gave a description of the function of this society, which has more than 2,000 members. The society aims to apply Christian virtues in the practice of medicine and official charity. He emphasized the usefulness of the Catholic medical unions, which at present are in operation in England, Belgium, Italy, Spain, Netherlands, Portugal, Tunis, Brazil, Colombia and the United States and which are being founded in Canada, Japan and Switzerland. To bring the Catholic medical unions of different countries in harmony, there was founded in Paris the secretariat of the medical unions of the different countries.

Bergmann, a member of the supreme hygienic board at Cleve, spoke on abnormal character. In psychopaths sex assumes a great role. Most psychiatrists forget that religious education could do a lot in improving sex ethics. For the Catholic academician the Aristotle scholastic philosophy is a possible solution of the great conflicts of psychic patients. It allows one to build up the doctrine of body and soul. Bergmann said that in psychoanalysis Freud has made advances which deserve recognition, but owing to its exaggerations and atheistic basis, and its idea destructive tendency, it is implicitly to be repudiated.

The Hungarian physicians who participated in the congress resolved to establish the Society of Hungarian Catholic Physicians this year.

Number of Medical Students at the Budapest University

In the new term, 540 students applied for registration of whom 97 were women. At the first term the number of applicants was 361 of whom 58 were women. Only 200 of these have been admitted (61.7 per cent of the male and 22.4 per cent of the female applicants). The minister of public instruction increased the number by 50 so that the first term students now number 250 while the rest of the applicants were instructed to register at the provincial universities, which had plenty of vacancies.

The Death of Professor Bernhard Vass

The Hungarian medical faculty has sustained a great loss by the death of Dr. Bernhard Vass, lecturer to the University of Budapest and director of the Budapest Bacteriologic and Public Hygiene Institution. The eminent bacteriologist and leader of the chemical analytic laboratory of the Polytechnic was in the service of the capital for twenty five years. He was removed in the field of bacteriologic research. His work in organizing

the Budapest public hygiene and bacteriologic institution is so exemplary that just this week a special commission from Italy came to study this institute as an example to follow. Likewise an invitation from Refik Bey of Turkey came to Professor Johann, director of this institute, to come to Turkey, with the permission of the Hungarian government and to direct the erection of a similar institute in Ankara, the chief purpose of which will be the training of medical officers of health. It was the tragedy of fate that Professor Vass could not live to see the opening of his institute, which is planned to take place early in November.

The Birth Rate in Budapest

According to recent statistics the birth rate is greatest in those districts of Budapest in which the population is the poorest and most illiterate, while it is the smallest in those districts in which the rich and well educated people live. The statistics reveal that in Budapest many more childbirths occur in the obstetric clinics than in private houses. On an average in the last five years three fourths of the births were in clinics and hospitals. In this respect Budapest resembles Paris. The fact that Budapest mothers prefer to go to public institutions is remarkable all the more because while the number of days of hospital attendance increased in the last fifty years four and a half fold, the increase of childbirths in public hospitals increased forty fold. The reason of this is to be sought in the unfortunate economic situation. It is much more pleasant for a wife to be confined at her own home, but she is much safer in a hospital or clinic and the whole thing costs her only a nominal sum. Eighty seven per cent of all illegitimate births take place in public institutions. One fourth of all children born in institutes are illegitimate. In Paris the proportion is still higher. In Vienna the rate of illegitimate births in institutes is 29 per cent while in Berlin it is 65 per cent, but including the total number of births the rate is 21 per cent. That the rate of stillbirths is considerably higher in institutions than in private homes is easily understood. For difficult labor women are taken to institutions. Even if the rate of stillbirths showed double, there would still be a smaller rate of stillbirths in institutions for at the beginning of this century the rate was 6/100, in later years it was scarcely 4/100. The rate in Paris is 11/100, in Berlin 6/100 and in Zurich 4/100.

Influence of Syphilis on History

Prof. Dr. Louis Nclam, the newly elected rector magnificus of the Budapest University, in his inaugural address discussed the influence which syphilis has exerted on the history of the world. He told his hearers with dramatic vigor that this new disease of the renaissance transformed the world. It separated England from the Roman Catholic church when King Henry VIII, who doubtless had syphilis, had a fierce controversy with Pope Clement VII, who refused to declare his marriage with Catherine dissolved. Had Catherine not brought to the world still born children and a girl, the later Queen Mary, with characteristic manifestations of congenital syphilis, Henry VIII would not have tried to hasten his union with Anne Poleyn. Pungent as usual in the hawthorn way, King Henry threw aside his connection with Rome. England became Protestant and instead of a spiritual power became a layal power. Protos or Nekam further explained how syphilis determined the ways of countries, nations, cultural currents and fashion. He told the names of those writers and artists who by reason of syphilis were ruined at a premature age. He mentioned that Dostoevsky and Oscar Wilde had syphilis. It caused a great flurry in the lay press that he named a celebrated Hungarian poet, László Ady, whose wonderful poems are translated in a hundred languages and who died several years ago at a relatively early age. Ady died in 1919 and his birthday celebrations were written just in the ten to fifteen years period which preceded his premature death.

Marriages

GEORGE BENJAMIN WISLOCKI Baltimore to DR FLORENCE CLOTHIER of Wainwood, Pa, February 13

WILLIAM P. PETRII Caro Mich to Miss Evelyn Chrysler of Wauhatchie at Toledo Ohio January 3

GEORGE JACOB BUSHONG Tompkinsville Ky, to Miss Carrie Hendrick of Indianapolis January 31

CLIFFORD LEE WILBOURN to Miss Lottie Mae Webber, both of Charleston S C January 20

LEROY I. GIBSON Pontiac Mich to Miss Lulu Flewelling in January at Toledo Ohio

LOGAN ELITS to Miss Arlene Dillon, both of Russellville, Ky in Marion January 27

HENRY B. MUSSINA to Miss Dora L. Kopp, both of Wilkesport Pa February 2

JOHN H. STUDEI Franklin, N Y to Miss Anna Jones at Sumner Pa February 25

FREDERICK B. MOOREHEAD to Miss Marjorie Maxwell, both of Chicago February 1

Deaths

Veranus Alva Moore * Ithaca N Y Medical Department of Columbian University Washington D C 1890 engaged in the investigation of infectious diseases for the bureau of animal industry, U S Department of Agriculture, 1890-1896 and chief of the division of animal pathology 1895-1896, professor of comparative pathology bacteriology and meat inspection 1896-1929 dean 1905-1929 and since 1929 emeritus professor of veterinary pathology New York Veterinary College, Cornell University member of the American Association of Pathologists and Bacteriologists formerly member and president of the school board for many years member of the board of health author of "Laboratory Directions for Beginners in Bacteriology" "The Pathology and Differential Diagnosis of Infectious Diseases of Animals" and others aged 71 superintendent of the Ithaca Memorial Hospital, where he died, February 11, of heart disease

George Pierce Twitchell, Greenfield Mass Harvard University Medical School, Boston 1882 member of the Massachusetts Medical Society and the Associated Anesthetists of the United States and Canada formerly on the staff of the Franklin County Public Hospital aged 75, died Dec 2, 1930

Carl W. Plumb * Grand Junction Colo, Denver and Gross College of Medicine, 1906 member of the American Psychiatric Association medical director and superintendent of the State Home and Training School for Mental Defectives, aged 51 died, January 19, of diabetes mellitus and nephritis

Thomas Holmes Walker, Philadelphia University of Pennsylvania School of Medicine Philadelphia, 1895 member of the Medical Society of the State of Pennsylvania, served during the World War on the staff of the Presbyterian Hospital, aged 59 died, February 2, of heart disease

John J. Reycraft, Petoskey Mich Detroit College of Medicine, 1891, member of the Michigan State Medical Society past president of the Emmet County Medical Society, on the staff of the Petoskey Hospital aged 63, was found dead in bed January 29 of cerebral hemorrhage

George Stephen Shattuck Los Angeles Michigan College of Medicine, Detroit 1881, professor of oral surgery and oral pathology in the department of dental surgery Detroit College of Medicine aged 89 died, Nov 30 1930 of chronic interstitial nephritis and bronchopneumonia

Charles I. Griffith * Washington D C Georgetown University School of Medicine Washington 1905, associate professor of pharmacology at his alma mater, served during the World War aged 53, died, Dec 21 1930, of essential hypertension and cardiac decompensation

Daniel R. Connell, Beloit Wis Chicago Medical College 1891 member of the State Medical Society of Wisconsin on the staff of the Beloit Municipal Hospital aged 62 died February 8 in St Anthony's Hospital Rockford, Ill, as the result of an injury received in a fall

Stephen Laurence Egart * Indianapolis, Indiana University School of Medicine Indianapolis, 1908, member of the Associated Anesthetists of the United States and Canada aged 58 on the staff of the City Hospital, where he died, February 6, of chronic myocarditis

Elmond Arthur Burnham * Washington, D C, Harvard University Medical School Boston 1894, member of the Massachusetts Medical Society, served during the World War aged 65 died February 11, in the Garfield Hospital, of cerebral hemorrhage

Cyril James Shiring, Pittsburgh St Louis University School of Medicine, 1929 resident physician at the Maternity Hospital Cleveland, aged 24 died, January 3, in the Mount Sinai Hospital, Cleveland, as the result of a traffic accident

Lettie Helen Woodruff, Rochester, N Y, University of Michigan Medical School Ann Arbor, 1877 member of the Medical Society of the State of New York aged 81, died February 11 of chronic myocarditis and arteriosclerosis

Delos Harvey Marcy, Williamsport Ohio, Ohio Medical University Columbus, 1902 member of the Ohio State Medical Association member of the Deercreek Township board of education aged 54, died, February 4 of heart disease

Frank August Sigrist, Baltimore University of Kansas School of Medicine Kansas City 1922 member of the Medical and Chirurgical Faculty of Maryland aged 36, died, January 27 in St Agnes Hospital of lobar pneumonia

Percival Ranney Bolton, Thomasville, Ga Medical Department of Western Reserve University Cleveland, 1889, Medical Department of Columbia College, New York, 1890, aged 65 died February 4 of angina pectoris

Frederick J. Wood * Cleveland Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University 1902 aged 52 died suddenly, January 24, in St John's Hospital, of cerebral hemorrhage

Karl Phillip Reefy, Elvira Ohio Eclectic Medical Institute Cincinnati 1906 member of the Ohio State Medical Association aged 50 died, January 24 in Cleveland, of arteriosclerosis hypertension and heart disease

Harrison A. Kitchen, Butler, Pa Jefferson Medical College of Philadelphia 1890, also a druggist, aged 63, died January 20 in the Butler Hospital, as the result of injuries received in an automobile accident

Grant S. Vorhees, Prescott Mich Baltimore University School of Medicine 1898, member of the school board, aged 60 died, January 9, in Miami, Fla, of chronic interstitial nephritis and mitral stenosis

Samuel T. Rutherford, Stratford, Ont, Canada, Victoria University Medical Department 1889, member of the American College of Surgeons, county jail physician, aged 66, died, Nov 29 1930 of heart disease

Julian Decatur Maynard, Wadesboro N C, University of North Carolina School of Medicine, 1908, aged 46, was found dead in his car, February 1, of chloroform, presumably self administered

James F. Tanner, Hartford, Conn Baltimore University School of Medicine 1898, aged 61, died, Nov 5 1930, in Stratford, of pernicious anemia, chronic nephritis and myocarditis

Alexander Marshall, Ashton, R I Medical Department of the University of the City of New York, 1891, member of the state legislature, aged 69, died February 12, of Hodgkin's disease

Laurel A. Summers, Wherton, Kan, Marion Sims College of Medicine, St Louis 1893, aged 64, was killed Nov 30, 1930 when the automobile in which he was driving overturned

Herbert Anderson White * Raymondville, Texas Chicago Homeopathic Medical College 1898 aged 61, died January 24 in the Mercy Hospital, Brownsville, of septicemia

John Henry Kane Lexington Mass, Long Island College Hospital Brooklyn 1885, formerly postmaster, aged 80, died February 5 of chronic myocarditis and bronchopneumonia

Hubert Granville Wilbur * Long Beach Calif, Harvard University Medical School Boston, 1890, aged 71, died, January 25, of injuries received in an automobile accident

John P. Briscoe Washington D C Georgetown University School of Medicine, Washington, 1905 aged 49, died, February 15, in the Garfield Hospital, of pneumonia

William Thomas Stokes Alpine Texas, University of Alabama School of Medicine 1908 served during the World War, aged 53, died, January 25, of angina pectoris

William J. Saunders, Muskegon, Mich. Saginaw Valley Medical College 1903, member of the Michigan State Medical Society, aged 58, died, in January, of heart disease

Franklin George Johnson, Sheridan Mo., Medical-Chirurgical College of Kansas City, 1901, aged 57, died, January 6, of infection of the spinal cord and paralysis

Thomas W. Breaux, New Orleans, Medical Department of the Tulane University of Louisiana, New Orleans, 1898, aged 58, died, January 17, of chronic myocarditis

Isaac Johnston Campbell, Clover S. C. Hospital College of Medicine, Louisville, 1905, state senator, aged 49, died suddenly, February 7, of angina pectoris

Patrick Joseph Murray, Toronto, Ont. Canada University of Toronto Faculty of Medicine 1927, aged 31, died, Dec. 10, 1930, in St. Michael's Hospital

James Johnston Gillespie, Pincher Creek, Alta., Canada Queens University Faculty of Medicine, Kingston, 1904, aged 52, died suddenly, Nov. 28, 1930

George Hilbard Setzler, Crossett Ark., Memphis (Tenn.) Hospital Medical College 1896, aged 66, died suddenly, Nov. 23, 1930, of heart disease

Lydia Higgins, Muskegon, Mich. University of Michigan Medical School, Ann Arbor, 1884, aged 82, died, January 31, of myocarditis and chronic nephritis

Byron M. Moulton, Springville Maine College of Physicians and Surgeons Baltimore 1894, aged 65, was found dead, January 28, of heart disease

Raffaele Maglione, Brooklyn Royal University of Naples Faculty of Medicine and Surgery Naples, Italy 1903, aged 53, died, in January, of heart disease

Joseph Hormidas Roy, Lowell Mass. School of Medicine and Surgery, Montreal, Que., Canada, 1893, aged 65, died, January 25, of diabetes mellitus

John Kean, Chicago Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, aged 98, died, Dec. 1, 1930, in Jacksonville Fla., of senility

George Pearn, Derrington Kan. New York Homeopathic Medical College and Hospital, 1894, formerly county coroner, aged 60, died, Dec. 14, 1930

Horace Garfield Dunham, New York Jefferson Medical College of Philadelphia 1913, served during the World War, aged 49, died, Dec. 6, 1930

Horace H. Thompson, Terre Haute Ind. Pulse Medical College, Homeopathic Cincinnati, 1886, aged 70, died, in January, of diabetes mellitus

William J. Shilliday, Hiles Wis. Detroit College of Medicine, 1891, aged 62, died January 16, in Rochester, Minn., of carcinoma of the colon

Samuel John Wylie, Columbus Ga. Columbus (Ohio) Medical College 1887, aged 67, died, January 20, of acute dilatation of the heart

Jeremiah W. Russell, Bellville, Ohio Starling Medical College, Columbus 1888, aged 71, was found dead February 4, of gastric carcinoma

Joseph Samuel Leslie, Tribune Kan. Barnes Medical College, St. Louis 1897, aged 68, died Dec. 27, 1930, of pulmonary tuberculosis

Mary S. Ertl, Los Angeles Hahnemann Medical College and Hospital Chicago, 1887, aged 75, died, January 12, of mitral regurgitation

Henry Westren Miller, Kansas City Mo. Western Homeopathic College Cleveland 1869, aged 85, died in December, 1930

William Herman Anderson, Littlefield Texas Bellevue Hospital Medical College New York 1890, aged 73, died Nov. 11, 1930

Johann F. E. Weiland, Fremont Neb. University of Colorado School of Medicine 1904, aged 68, died Dec. 6, 1930

William Young Fullerton, Port Williams N. S. Canada Bellevue Hospital Medical College 1872, died Dec. 9, 1930

John McLean Oniltha Ont. Canada (opened Ontario 1876) medical health officer, aged 80, died Dec. 4, 1930

John Barnes Rosson, Tuhira Calif. Medical College of Ohio Cincinnati 1872, aged 80, died Nov. 15, 1930

Gilman Davis, Portland Maine Medical School of Maine, Portland 1893, aged 61, died Nov. 7, 1930

Anton Anderson, Los Angeles Denver College of Medicine 1895, aged 74, died Dec. 17, 1930

Bureau of Investigation

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

Sun Laxative Cold Breakers—The S. Pfeiffer Manufacturing Company of St. Louis, Mo., consigned a quantity of Sun Laxative Cold Breakers in December 1928, which were declared misbranded. Analysis showed the tablets to contain acetanilid extracts of a laxative plant drug traces of arsenic and cinchona alkaloids. It was falsely and fraudulently recommended as a cure for influenza and malaria. In December, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17059, issued November 1930]

B-L Cold and Grippe Tablets—The Blood-Life Company of Atlanta, Ga., shipped in October 1928, and January, 1929, a quantity of B-L Cold and Grippe Tablets that were declared misbranded. Analysis showed the tablets to contain 1 grain each of acetanilid, together with a quinine compound, caffeine camphor monobromate alone and a resin. The claim that the product was a remedy for influenza was declared false and fraudulent and in June 1929 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17067, issued November, 1930]

Mathieu's Nervine Powders—Favreau and Collette of Spencer, Mass., consigned a quantity of Mathieu's Nervine Powders that were declared misbranded. When analyzed, the powders were found to consist essentially of acetanilid, baking soda and caffeine. The claim that they were a remedy for influenza and neuralgia was declared false and fraudulent and in December 1929 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17069, issued November, 1930]

G. G. Germicide—Rose Rockwood of Belgrade, Maine shipped in October, 1929, a quantity of G. G. Germicide that was declared adulterated and misbranded. Analysis showed the product to consist essentially of formaldehyde, extracts of plant drugs including sassafras alcohol and water. Bacteriological examination showed that the article was not antiseptic in the dilutions recommended on the label. It was declared adulterated because it fell below the professed standard under which it was sold—that is, it was sold as a germicide when it was not. It was declared misbranded because the claim that it was a remedy for influenza, headache, neuralgia, bronchitis, indigestion, diarrhea, etc. was false and fraudulent. In February, 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17086 issued December, 1930]

Success Cold Tablets—The Walgreen Company, Chicago Ill. shipped in October 1929 a quantity of Success Cold Tablets that were declared misbranded. Analysis showed the product to contain acetanilid, some laxative plant drug extractives with wintergreen flavor. The claim on the label that the product was a remedy for influenza was declared false and fraudulent and in February 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17094 issued December, 1930]

Muco-Solvent—The Hiesig Ellis Drug Company and the Van Fleet Ellis Corporation both of Memphis Tenn. shipped a quantity of Muco-Solvent and Muco-Solvent Salve between August 1928 and August 1929 that was declared misbranded. Muco-Solvent was found to consist essentially of alcohol and extracts of plant drugs glycerin alcohol (27.6 per cent by volume) and water. Muco-Solvent Salve was found to consist essentially of petroleum and volatile oils including camphor, menthol, turpentine and eucalypti. Muco-Solvent was declared adulterated because it was a laxative and a cathartic.

Correspondence

"STUDY OF HUMAN AMEBIASIS BY MEANS OF THE MOTION PICTURE"

To the Editor—In THE JOURNAL January 17, there appeared an article entitled "Study of Human Amebiasis by Means of the Motion Picture" by Barrow and Woodard, which has placed me in a very embarrassing position.

After years of intensely hard work Clifford Dobell was able to send me in Palo Alto cysts of three separate strains with compatible bacterial associations. After cultivation I furnished the California School of Tropical Medicine with live culture. I also expected a promise from Dr. Reed that the history of the strains should not be given out until Dobell's work on them should be published.

Barrow has given an entirely imaginary and absolutely erroneous origin for one of these strains that he took to Los Angeles. It is very possible that he did not have a human strain at all. Two of my three strains were of monkey origin and I have excellent reasons for believing the strain taken to Hollywood was not a human one. One might have expected that Clifford Dobell would have been approached with a view to obtaining permission to publish an article on the fruits of his labor—but, on the contrary, his name is not even mentioned in the article in question. I have had to apologize to Dobell for my share in making this distorted contribution possible.

THE COFFEY-HUMBER PATENT

To the Editor—Referring to Dr. MacDonald's letter in THE JOURNAL, January 10, may I suggest that Dr. MacDonald procure from the Chemical Foundation the complete photostated file of the Coffey-Humber patent transaction. He will see that the patent office in April 1930 refused to grant the patent in a masterly report on Coffey's preposterous claims, which were annihilated one by one by a patent examiner who dealt with them in a truly scientific fashion. He will also see (and it may surprise and shock him as much as it did me) that Ray Lyman Wilbur wrote the Patent Office requesting specially expeditious handling of the matter on account of his responsibility for the medical care of the American Indian and the Alaskan Eskimos. His next interesting discovery will be that Dr. Coffey's claims were resubmitted July 1, 1930, and the patent granted on July 2—the example of speed and efficiency which is a true tribute to the Great Engineer and his strong, silent way of getting things done.

JOHN M. REHRISCH, M.D., San Francisco

THE WIRING OF ANEURYSMS

To the Editor—Since the work of W. M. Millar (*The Use of Wires in Blood Vessel Surgery* Proc Soc Exper Biol & Med 28:193 [Nov.] 1930), who showed experimentally that zinc wire causes a quicker clotting than any other wire when placed in the thoracic aorta, I have had occasion to wire in patients two aneurysms of the ascending and transverse arch. One of the greatest difficulties was to find a source of supply for this wire but finally I was referred to the Hudson Wire Company Ossining, N. Y. which furnished me with zinc wire electrically prepared and virtually pure testing 99.99 pure zinc. The wire we used was number 23 B and S gage. It was thoroughly cleaned first and then roughened by abrading with coarse emery paper so that the circulating blood would strike these roughened surfaces and thus form the nucleus for a clot. It was found that a 17 gage lumbar puncture needle the point

when it was not, it was declared misbranded, first because the amount of alcohol it contained was incorrectly stated and because the statement that it was a remedy for catarrh, sore throat, tonsillitis, etc., was false and fraudulent. Mucic Solvent Syrup was declared misbranded because the claim that it was a remedy for piles, boils, croup, asthma, bronchitis, whooping cough, etc., was false and fraudulent. In January, 1930 judgments of condemnation and forfeiture were entered and the court ordered that the products be destroyed.—[Notice of Judgment 17087, issued December 1930]

Nervac—The Nervac Medicine Company, Bristol, Va., shipped in March 1929 a quantity of Nervac that was declared misbranded. Analysis showed the product to consist of extracts of plant drugs including laxatives, ethylic acid, glycerin and a small amount of alcohol flavored with wintergreen. While the label intimated that the preparation contained golden seal, no golden seal was found. Further, the amount of alcohol declared on the label was misstated while the curative claims to the effect that the preparation was a blood purifier and a remedy for liver, kidney and stomach disorders and nervous prostration were declared false and fraudulent. In February 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17088, issued December 1930]

Da-Lee Mouth Wash—The Da-Lee Chemical Company, Inc., shipped from Baltimore in November 1929 a quantity of Da-Lee Mouth Wash that was declared misbranded. The preparation was found to consist essentially of baking soda, small amounts of glycerin and volatile oils with 36 per cent of alcohol and water. Biological examination showed that the Da-Lee Mouth Wash was not antiseptic in the dilutions recommended further. The claim that the product was a remedy for catarrh, tonsillitis, pyorrhea, etc., was declared false and fraudulent. In February 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17089, issued December, 1930]

Selso Headache Powders—The Standard Manufacturing Laboratories of Macon, Ga., shipped in July 1928 a quantity of Selso Headache Powders that were declared misbranded. Analysis showed the powders to contain aspirin, phenacetin, and caffeine. The product was declared misbranded first because of the false and misleading statement that the powders were safe, it was also declared misbranded because it was falsely and fraudulently claimed that the powders were a remedy for catarrh, neuralgia, female pains, sleeplessness, tonsillitis, rheumatism, etc. In October, 1929 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17090, issued December, 1930]

Marvel Chemical Tablets—The Marvel Company, New Haven, Conn., shipped in September, 1929 a quantity of Marvel Chemical Tablets that were declared misbranded. Analysis showed the tablets to contain boric acid, compounds of aluminum, iron, zinc and calcium, sulphates, carbonates, tannic acid and thymol. The claim on the label, that the product was a solution which would check infection and was of value for local discharges was declared false and fraudulent. In February 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17098, issued December 1930]

Fritch's Vegetable Soap—J. A. Fritch, St. Louis, Mo., shipped in January, 1930 a quantity of Fritch's Vegetable Soap that was declared misbranded. Analysis showed the product to be essentially a soap made from palm oil and perfumed with oil of citronella. Bacteriological examination showed that the article was not antiseptic. The claims on the label that the product was nature's own remedy and relief for skin diseases and that it was both antiseptic and germicidal were declared to be false, misleading and fraudulent. In April 1930 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[Notice of Judgment 17160, issued January 1931]

of which had been beveled down, was suitable for entering the aneurysmal sac. In no case was any current passed through the wire, since Millar showed that clotting takes place with equal facility whether the current is passed through or not, in fact, he felt that the current may possibly be detrimental.

Since using the wire in these cases I have had occasion to furnish some of it to a local surgeon and also to send some to a colleague in Omaha.

FERDINAND C LEE, M.D., Baltimore.

PERSISTENT IRRITATING VAGINAL DISCHARGE

To the Editor—Recently I have seen several women who complained of a severe irritating vaginal discharge. On examination a third degree retroversion and badly ulcerated cervix was found. I treated them a number of times with mercurochrome 220 soluble and tampons and then cauterized the cervix. These healed over with new tissue and looked perfectly normal. I also inserted pessaries to correct the retroversion. The discharge cleared up in all of them for a time but they have all been back complaining that it has returned. It is not as bad as before cauterization but it is still bad enough to cause trouble. Kindly advise me why this condition has returned and what I can do to clear it up. Please omit name.

M.D. Iowa

ANSWER—Most likely the discharge in these women is associated with *Trichomonas vaginalis* because this organism is frequently found in cases of troublesome and recurring leukorrheal discharge. Attention was called to this condition in this country by DeLee ten years ago and again by Greenhill three years ago. The diagnosis is easily made by examining a fresh drop of the secretion either as a hanging drop or diluted with salt solution on a glass slide. The drop of secretion usually consists of a large number of leukocytes and bacteria, many epithelial cells and many trichomonads. The parasites are spindle shaped or pyriform, and they are larger than a polymorphonuclear leukocyte but smaller than an epithelial cell. With the ordinary dry high-power lenses the organisms may be readily seen because of their motility. Greenhill says "The clinical picture produced by the *Trichomonas vaginalis* when it is pathogenic is rather uniform and striking. The patients complain of a profuse discharge which in about half the cases is associated with a burning or itching sensation in the vagina and on the vulva. In some cases the irritation is so severe that sleep is disturbed. The patients often scratch the external genitalia and an inflammatory reaction similar to intertrigo may result. Often the discharge has a very disagreeable and penetrating odor. On external examination small condylomas, either flat or pointed, may occasionally be seen but the introitus is usually reddened. The entire vaginal mucosa all the way up to the vault is found to be reddened and sometimes it is fiery red. In the introitus the redness is usually diffuse but in the vagina it may be diffuse or patchy. Often the vaginal mucosa has a deep orange color and usually it presents the appearance of an inflammatory condition. For this reason the clinical picture is called *Trichomonas vaginalis* vaginitis. The region of the external os is also usually red and it occasionally bleeds readily even though there is no erosion. No inflammatory condition, however, is found above the external os. The vagina contains a very large amount of greenish, yellow, foamy pus which looks like gonorrheal pus but sometimes the discharge is thin and watery. Most of it is found in the vaginal vault and it may have an acid alkaline or amphoteric reaction. Some patients are nervous due to the constant irritation, sleeplessness and fear of having contracted a venereal disease. Many go from doctor to doctor and while they secure temporary relief they are not cured. Quite a few women are unclean in their personal habits but by no means all.

Greenhill's present treatment is as follows: The vulva and vagina are thoroughly scrubbed with tincture of green soap the soap is washed out with mercuric chloride or tap water and the vagina is thoroughly dried. Hexyl alcohol is then applied all over the vaginal mucosa and a tampon saturated with glycerin is inserted into the vagina. A second dry tampon is inserted to prevent leakage of the glycerin. This treatment is continued every second day for at least four times or until

two successive hanging drop examinations fail to show the trichomonas organisms. After these treatments are completed the patient takes a douche once a day for about two weeks using an ounce of tincture of green soap to a quart of warm water. Since recurrences frequently take place just before or after a menstrual period, it is advisable to treat the patient during one or more menstrual periods following the first course of treatments (Greenhill, J. P. *Am J Obst & Gynec* 16:870 [Dec.] 1928).

The vaginal discharge described in these patients may be due to other conditions, especially thrush. In this case the mycelia may likewise readily be detected in fresh drops of secretion. This discharge may be cleared up by means of silver nitrate or a borax-glycerin combination.

MAINTENANCE OF CONSTANT PULSE PRESSURE

To the Editor—What is indicated when a pulse pressure is nearly always the same although the diastolic pressure and the systolic pressure vary? The reading may be 200/100 190/90 occasionally 180/80 or perhaps when the systolic pressure is unusually high a reading of 232/120 that is, I may get a pulse pressure of 112. I have had also 210/100. After administering amyl nitrite I had 170/72 but rarely do I have less than 100 pressure never below 96 but when the systolic pressure reached 232 the pulse pressure has reached 112 the diastolic being 120. Please omit name.

M.D.

ANSWER—In general, diastolic pressure represents resistance encountered in the vascular tree and is usually stable. Pulse pressure represents blood flow, it is the effective part of blood pressure so far as circulation is concerned and may vary considerably with changing conditions representing need for circulation, systolic pressure represents total heart work for the moment and varies greatly. Under normal conditions and in the individual case, the three tend to bear a definite relationship to one another, i.e. diastolic pressure is two thirds systolic pressure and twice pulse pressure.

A relatively high pulse pressure, 100 mm in this instance usually represents an increased demand for blood flow. It is frequently seen in thyrotoxic states associated with long standing adenomatous goiter with low grade intoxication and associated vascular damage. Under these conditions other evidence of hyperthyroidism may possibly be elicited, a small nodule in the thyroid gland may be palpable, the metabolic rate somewhat increased above normal, nervousness and tremor may be evident and the occasional appearance of glycosuria would substantiate such a diagnosis. It should be understood however, that all the observations enumerated may be obscure or may be present in varying combinations.

A pulse pressure of 100 mm is also frequently observed in aortic regurgitation. In this instance the vascular tension is not sustained during diastole, the blood regurgitating into the left ventricle through damaged aortic cusps. A diastolic murmur may be heard in the second right interspace or along the left border of the sternum and left hypertrophy is usually demonstrable. If compensation is well maintained, few symptoms if any may be present.

The diastolic readings given might be interpreted as indicating some grade of hypertension although such variation in diastolic pressure with occasional normal readings is unusual. Great care should be taken in making diastolic readings. The point at which the sharp first tone gives way to a dull note is accepted as the index of diastolic pressure and while this is the nearest auscultatory event that may be detected or near the true diastolic pressure level there is known to be a considerable error inherent in this determination. In some individuals also the change from the high to the low pitch may be difficult to determine and a 10 mm. error may be present under such circumstances.

In the present instance diastolic pressures varying from 60 to 100 mm as reported are not unusual since diastolic pressures tend to be fairly constant in the individual patient.

PREVENTION OF HEREDITARY PROGRESSIVE MUSCULAR ATROPHY

To the Editor—Can you give me any information regarding the prevention of hereditary progressive muscular atrophy in the offspring of an affected father who has two of its children? I have been able to find a list of the only hereditary progressive muscular atrophy.

OSCAR SAUNDERS, M.D., Green Park, W.

ANSWER—There is no possible way of preventing the development of progressive muscular atrophy in the offspring of an affected father. A child has to be used as a carrier of the disease in the child is destined to develop it.

QULRILS AND MINOR NOILS

JOHN A. M. A.
March 1, 1911

TREATMENT OF SYPHILIS
To the Editor—A man aged 24 white and married seen Oct 7 1930 showed a secondary syphilitic rash of a maculopapular variety on the palms of the hands chest penis and soles of the feet. No evidence of a primary lesion could be uncovered nor could a history of one be obtained. Diagnosis was confirmed by a Kahn test which returned 4+. Anti-syphilitic treatment was instituted at once 0.3 Gm of neoarsphenamine being given intravenously. Mercurialunctions were started. The following week the patient reported that in hour after receiving the intravenous medication he experienced a chill which lasted about twenty minutes. Other symptoms were not experienced. At this visit 0.6 Gm of neoarsphenamine was given intravenously. An hour later while the patient was still in my office he experienced a moderately severe nitritoid reaction evidenced by continued and severe chills intense headache and rhe pain in the joints and vomiting. All of which lasted about twenty five minutes. I discontinued the mercurialunctions at the end of this experience. I continued the intravenous injections at the end of which the Kahn reaction was 2+. Would you advise giving this patient a course of bismarsen sulpharsphenamine intramuscularly or another course of endobismuth intramuscularly in conjunction with mercurialunctions? If this is published kindly omit name.

ANSWER—The first reaction experienced by this patient to an injection of 0.3 Gm of neoarsphenamine might properly be interpreted as a so called Herxheimer reaction or therapeutic shock resulting from the flare up induced by the rapid action of a spirochete destroying drug. The reaction following the second injection however while perhaps also explainable on the same grounds is equally to be accounted for by other and more significant possibilities from the standpoint of the general management of the patient. The reaction is described as not strictly spending a nitritoid reaction. Instead it is to be classified as one of the general toxic reactions for which the causes vary all the way from improper technique of preparation and administration of the drug to decided and unusual idiosyncrasy on the part of the patient. Accepting the possibility that the technique of administration is at fault attention should be drawn to the fact that reactions of this type occur in patients who have been allowed to eat considerable quantities of food within several hours of their treatment. They also follow reaction and shaking of the neoarsphenamine solution in the process of preparation, which enormously increases the toxicity of the drug. They likewise occur following rapid injection of the drug a common fault in ordinary practice. Nitritoid crises, while comparatively common with arsphenamine are rare with neoarsphenamine. Any reaction following the intravenous administration of the drug which involves a chill likewise suggests the possibility of bacterial or other impurities in in unsatisfactorily prepared water or a technique that is not completely aseptic.

It is difficult to understand just what is meant by endobismuth injections which were substituted for the neoarsphenamine, following the second reaction. If by endobismuth is meant the intravenous administration of a bismuth preparation it should be pointed out that the Council on Pharmacy and Chemistry has wisely ruled that intravenous bismuth medication, in the present state of knowledge of the drug is not a justifiable form of procedure because of the narrow margin that exists between the therapeutic and the toxic dose of bismuth by the intravenous route. It might also be remarked parenthetically that it is unwise to govern the therapeutic procedure in any case of early syphilis apparently entirely by the serologic response. While a decrease in positiveness of the Kahn test from 4 plus to 2 plus is perhaps evidence of therapeutic effect it should not be used as a guide to the continuance or discontinuance of treatment. The proper management of an early case consists in the administration of a standard amount of treatment, determined by extensive clinical practice and compressed within a period of time ranging from one year to eighteen months and in any case extending if possible a year beyond the disappearance of the first symptom and sign of the disease. All this is quite irrespective of the reversal of the blood Wassermann reaction or the precipitation test.

With regard to the further mode of procedure in this case, the questioner should first recall his technique and decide whether or not there have been remediable faults which if recognized and corrected would permit the resumption of neoarsphenamine by a proper technique. If it is decided that the reactivity of the patient is due to idiosyncrasy rather than to error the relative merits of bismarsen (sulpharsphenamine bismuth) sulpharsphenamine and silver arsphenamine deserve consideration. Bismarsen, if given twice a week intramuscularly in the maximum adult dose of 0.2 Gm for a series of forty or more injections without a rest interval, offers reasonable prospect for a lasting therapeutic result.

Sulpharsphenamine, while well tolerated by patients is known to produce the highest incidence of exfoliative dermatitis of any of the arsphenamine groups in use at the present time. Silver arsphenamine, while it frequently produces immediate reaction has in all probability advantages over neoarsphenamine from the standpoint of therapeutic effectiveness and, if properly given, may be well tolerated by this patient. Bismarsen probably offers as low an incidence of complications as any of the drugs that are here suggested. If it is found that neoarsphenamine could be resumed the maximum dose should not exceed 0.6 Gm, at weekly intervals, and a smaller dose, such as 0.45 Gm, at intervals of from three to five days, would be preferable. The series of injections should reach twenty for the first course and from ten to twenty for the second course and a bismuth preparation of the readily absorbable type, though not necessarily a water soluble salt, may be given simultaneously and intramuscularly with the injections of neoarsphenamine intravenously. If bismarsen is used it is of course not necessary to administer a bismuth salt though the bismarsen course might well be followed by the use of bismuth preparations. Mercurialunctions in the patient will take them conscientiously, may be reserved for a post-arsphenamine treatment course. In general, an effort should be made to reach an arbitrary limit of thirty five or forty arsphenamine injections and perhaps four courses of a bismuth salt intramuscularly.

It should be realized that the delay in getting this patient treatment under way and the reduction in effectiveness brought about through the attempt to meet the complications has materially reduced the probability of a curative result and it is therefore doubly essential that this patient be kept under periodic observation throughout life. It is, moreover, necessary that a spinal fluid examination be performed with a full report on Wassermann cell count globulin and colloidal tests within the first year of treatment in order to forestall the possibility of asymptomatic neurosyphilis.

UNUSUAL WRITING PHENOMENON

To the Editor—Will you be kind enough to give me information concerning a rather unusual condition in a girl aged 7 years who had a marked internal strabismus which was partially corrected by surgery and glasses and who is rather backward in her classes owing no doubt in part to the visual defect. The patient was referred to me for a neurologic and mental investigation. The patient spells her name correctly but when told to write her name she begins at the right side of the page and writes the name beginning with the last letter and ending with the first letter which when complete places the letters in proper order. Her mother states that she also reads from the right to the left of the page. She is left handed. In looking up the matter in all available literature the nearest approach I find to this case is the condition of so-called mirror writing. It has been said to occur in defectives and those who are left handed.

ANSWER—The type of writing described is not that of mirror writing. Nevertheless at the age of 7 not much can be said about the type of reading and writing that a child may do. It is possible that she has a diffuse brain lesion and that special tutoring may cause this peculiar style which apparently has not been described in the literature. If the defect continues as the child grows older and reads more than the simple word combinations it will be an interesting phenomenon for careful and detailed investigation.

EFFECTS OF CHLORPICRIN

To the Editor—I am inquiring for the late effects of chlorpicrin on a person who worked in a plant that manufactured this gas. This man worked in the factory at Edgewood Arsenal Maryland in 1918 for three months. He states that he had always been quite well before that time but while working there he was attacked with abdominal cramps diarrhoea cough and weakness which affected most of the other employees. He was discharged from this plant after three months but ever since he has had similar attacks of distress. He has been examined at a number of places by many competent men some of whom have told him he had gastric or duodenal ulcers although he has never had any positive roentgenographic evidence. In the immediate vicinity of this factory was made also mustard gas and phosgene and I wish you would tell me whether any of these three poisons could cause a continuation of these complaints or any other trouble over such a long period of time.

ANSWER—Chlorpicrin in terms of toxicity stands between chlorine and phosgene but partakes of the qualities of each. The characteristic primary and principal tissue reactions are found along the respiratory tract, culminating in pulmonary edema. Chlorpicrin however, is known as a vomiting gas the significance of vomiting is of course trivial in comparison with pulmonary edema. All the symptoms noted in this case

MD Minnesota

may arise as acute manifestations of chlorpicrin poisoning, but their intermittent recurrence is not in keeping with concepts of a chronic lesion, particularly in the absence of renewed exposure.

The prevailing opinion is that gases such as phosgene, chlorine and chlorpicrin do not produce chronic lesions. To the contrary, a small amount of evidence indicates that the prolonged intake of such gases as chlorine may lead to emphysema or to chronic inflammation of the respiratory membranes, manifested chiefly by persistent severe coughing and obviously inflamed membranes and eventually by fibrosis observable on roentgen examination. Similarly, acute phosgene poisoning has been followed by sequelae causing total and apparently permanent disability.

In one instance, two industrial workers were exposed apparently, to phosgene, from the accidental production of this gas in industry. One man promptly died from pulmonary disorders associated with hepatitis. The second worker recovered from his acute lesions but in the ensuing ten years developed an extensive fibrosis, multiple arthritis a duodenal ulcer and some poorly defined gallbladder disease. Proof is lacking that a cause and effect relation exists in this situation. In a general way it is believable that any severe intoxication exacts some permanent toll from the life and well being of every injured individual.

In the present instance it is probably impossible to establish incontrovertibly that chlorpicrin is the cause of the condition described.

F. P. Underhill described the physiology and the treatment of poisoning with lethal war gases in THE JOURNAL, Aug. 30, 1919, p. 686.

PAIN IN BACK FROM INFLAMMATION OF MUSCLES

To the Editor—A man aged 39 was hit in the right lumbar region by shrapnel in France about 1915. Quite a number of pieces were removed at the time and now there are twelve or fifteen pieces about $\frac{1}{16}$ inch in diameter left scattered through the lumbar muscle. One of the vertebrae was injured at the time and it is out of line so that it shows plainly on the roentgenogram. This now brings us to the problem. The patient complains of severe cramping pains in these muscles. He is free from pain for weeks or months and then he has a recurrence of these pains. He has used electricity heat liniments poultices and various sedatives and analgesics. Nothing cures him. He now wears an abdominal support. Is there any treatment?

HENRY BAER M.D. Seattle

ANSWER—A light back brace of the Taylor or Goldthwait type and physical therapy, including radiant heat gentle massage and diathermy might be of benefit.

TREATMENT OF BRITTLE CUTICLE

To the Editor—I am writing to ask for some possible remedy for hardened and brittle cuticles with which I seem to be afflicted especially during the winter months. This may be a trivial query but it is an annoying condition and I would appreciate any suggestion. I had used a proprietary compound called Cutex with some relief. This seem to be an expensive preparation 35 cents for several cubic centimeters and I rather think a formula for it is simple. Kindly omit my name should this be answered through THE JOURNAL.

M.D. New York

ANSWER—The liquid used to soften the cuticle of the nail fold is probably a solution of potassium or sodium hydroxide. This is not a good thing to use because of the possibility of becoming sensitized to it and developing a dermatitis of the nail fold with consequent deformity of the nail. It would seem much wiser to prevent the drying of the skin by frequent use of a good cold cream or a borated cold cream (10 per cent) or one containing from 3 to 5 per cent of salicylic acid.

USE OF CAUSTICS IN TREATMENT OF CANCER

To the Editor—As a matter of information will you answer the following question: Does modern medicine approve of zinc chloride being used in any form in the treatment of cancer? We have in this community an M.D. who is using one preparation of zinc chloride promiscuously in the treatment of carcinoma epithelioma and various benign neoplasms and we are seeking information either in approval or disapproval of this treatment. Kindly omit name and town.

M.D. Kansas

ANSWER—The use of zinc chloride and similar caustics in the treatment of cancer has been practically abandoned by all except the cancer cure quacks. Such caustic are difficult to control so that there is destruction of healthy as well as of malignant tissue their action is slow thus unnecessarily prolonging the pain of removal. Much better results can be obtained by the judicious use of surgery when the growth is operable or by the use of radium and x rays when the disease

has advanced beyond the chance of its complete removal. The use of such caustics has been abandoned also by the progressive dermatologists in the treatment of small epitheliomas of low malignancy, they use, instead, radium, x rays, or coagulation with high frequency currents. The cosmetic and therapeutic results of the latter are much better than those following the use of caustics.

THE AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Its Organization, Function and Objectives

WALTER T. DANNIUTHIK, M.D.
NEW YORK

The American Association of Obstetricians Gynecologists and Abdominal Surgeons the American Gynecological Society and the Section of Obstetrics Gynecology and Abdominal Surgery of the American Medical Association each elected three members to comprise the American Board of Obstetrics and Gynecology which was created and organized in September 1930. Membership on the Board is limited to the representatives of the three national societies and the members serve as both directors of the corporation and as examiners. The preliminary plans for the creation of the board encompassed three years time and involved the serious consideration of many details and possibilities as well as a study of the history and experiences of the American Board for Ophthalmic Examinations and the American Board of Otorhinology. The American Board of Obstetrics and Gynecology is particularly indebted to the latter organization for much helpful advice and cordial cooperation.

To justify the existence of a new medical organization its proponents must be prepared to advance more than mere ideas for its activities. They must have a definite objective in view not legislative or restrictive but educational and constructive. There is no need for further standardization or regulation of the medical profession and it is well to emphasize that it is impossible that the American Board of Obstetrics and Gynecology shall ever eventuate in an oligarchic group, claiming to exercise a dictatorial influence. The work of the board should be regarded and accepted as the coordinated effort of the three national organizations to elevate the plane of obstetric and gynecologic practice rather than as the operation of an arbitrary plan formulated by its members.

It has been stated that the present uncontrolled status of specialism will not be permitted to continue indefinitely. If medicine itself does not react to professionalize its specialties

state will." From every quarter comes the plea that the medical profession make a distinction between qualified and pseudo specialists. One of the state medical societies has gone so far as to memorialize its board of regents, recommending that the state establish some method for the regulation of specialists. The public, lay and medical, are entitled to ask what particular qualifications a specialist possesses, and by what authority he so designates himself. The term 'specialist' carries with it the implication of superior training and a background of extensive clinical experience. Unfortunately in many instances a few weeks' attendance in a clinic, at home or abroad or merely the individual's intellectual dishonesty has been responsible for deliberate misrepresentation and served as a pretext for the genesis of the self-styled but incompetent specialist.

The hospitals which exist solely by virtue of the services rendered by the members of their medical staffs must participate in the stabilization of practice in the specialties but under the circumstances as they have existed in the past not even these institutions themselves have had any criteria for evaluating the capabilities of their staff members, except in the field of ophthalmology or otolaryngology.

Although all licensed physicians are legally empowered to treat any and all diseases, it must be conceded that the undergraduate's education unless supplemented by thorough postgraduate training is totally inadequate for special practice. No physician is warranted in posing as a specialist unless he is really expert in his chosen field, and the essential fitness and skill can be acquired only by intensive study, prolonged training and wide experience. The necessity for the establishment of standards of qualification to fix the requirements for legitimate specialization seems self-evident. The practice of obstetrics and gynecology has been a prolific field for the origin of numberless mushroom specialists and has contributed its share to the disrepute into which specialization has fallen. Our British colleagues have also apparently come to a realization of these facts as they have recently organized the British College of Obstetricians and Gynecologists, which has for its chief object the institution of a postgraduate diploma in obstetrics and gynecology.

The principal activities of a board of examiners in any of the specialties should be devoted to encouraging and inducing potential specialists to prepare themselves thoroughly to persuading medical schools and hospitals to provide adequate facilities for special training, and to put the stamp of approval on qualified practitioners. It was with the intent of supervising not controlling the practice of obstetrics and gynecology by specialists that the American Board of Obstetrics and Gynecology was organized. There is no desire on the part of the board to curtail in any way the professional responsibilities that any licensed practitioner may care to assume. In fact the board is powerless in this respect, even if it had such an inclination. Neither does it pretend to imply that any distinguished or well-qualified specialist in obstetrics or gynecology requires a further testimonial of his proficiency. Its principal purpose is to encourage the study, improve the practice, and advance the cause of obstetrics and gynecology, subjects that should be inseparably interwoven and to grant and to issue to physicians duly licensed by law, certificates or other equivalent recognition of special knowledge in obstetrics and gynecology. The chief function of the board is to arrange control and conduct examinations designed to test the qualifications of voluntary candidates for a certificate to be conferred by the board. The certificate issued, however, does not of itself confer, or purport to confer any legal qualification, license or privilege.

The submission of operative case records and the assurance of a certain degree of mechanical skill alone can by no means be accepted as evidence of an individual's qualifications to practice obstetrics and gynecology as a specialty and the work of the board will not duplicate or conflict with the function of any other existing organization. The applicant's professional

and personal character, general training, knowledge of pathology, familiarity with the literature, and actual experience in his chosen field must all be taken into account and assessed. The requirements and scope of the examination are adjusted so that the competent man can be easily accepted and the unqualified one will never be certified. The examination includes

(1) a survey of the candidate's professional career, with particular reference to his special training and postgraduate work in obstetrics and gynecology, (2) estimation of the extent of his clinical experience, (3) an inquiry into his surgical judgment, (4) a determination of his familiarity with important contributions to current obstetric and gynecologic literature, (5) a test of his knowledge of obstetric and gynecologic pathology, both gross and microscopic, (6) a review of his general knowledge and utilization of modern diagnostic measures and therapeutic resources in the field of obstetrics and gynecology, and (7) a summary of his contributions to the progress and advancement of the specialty, by his educational activities, actual teaching experience and meritorious scientific articles appearing in periodicals exercising due editorial revision.

While the conferring of a certificate is only incidental, it is logical to expect that the national obstetric and gynecologic societies which have participated in the organization of the board and are sponsoring its activities will attach considerable importance to the certificate and that the medical and lay public, including hospital trustees, will adopt the certificate from this board as a means of discriminating between those who are well qualified for staff appointments as specialists in obstetrics and gynecology, and those who are not. The list of certificate holders will be published yearly, and each one will be specially designated in the Directory of the American Medical Association.

All members of the board serve entirely without compensation, and the application fee is consistent with the cost of the certificate, the expenditures involved in conducting the examinations, and legitimate overhead expenses.

580 Park Avenue

ADDITIONAL HOSPITALS AND LABORATORIES APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals and laboratories since the publication of the last previous list in THE JOURNAL, Oct. 11, 1930.

Hospitals Approved for Intern Training

Norwood Hospital Birmingham Ala.
St. Joseph's Hospital Phoenix Ariz.
Glendale Sanitarium and Hospital Glendale Calif.
Cedars of Lebanon Hospital Los Angeles
Lawrence and Memorial Associated Hospitals New London Conn.
William W. Backus Hospital Norwich Conn.
Lloise Infirmary Flore Mich.
Bryonne Hospital and Dispensary, Bryonne N. J.
Ideal Hospital Endicott N. Y.
Mary Immaculate Hospital Jamaica N. Y.
Morrisania City Hospital New York
St. Joseph Hospital Syracuse N. Y.
Duke Hospital Durham N. C.
Mercy Hospital Canton Ohio
Homeopathic Hospital Providence R. I.
Providence Sanitarium Waco Texas
Shanghai Sanitarium and Hospital Shanghai China

Hospitals Approved for Residencies in Specialties

Barlow Sanitarium Los Angeles
Cedars of Lebanon Hospital Los Angeles
Macon Hospital Macon Ga.
St. Luke's Hospital Chicago
Macon County Tuberculosis Sanatorium Decatur Ill.
Touro Infirmary New Orleans
Mercy Hospital Jackson Mich.
Montefiore Hospital Country Sanatorium Bedford Hills N. Y.
Cenese Hospital Rochester N. Y.
Knoxville General Hospital Knoxville Tenn.
Nashville General Hospital Nashville Tenn.

Pathologists Conducting Approved Clinical Laboratories

H. M. Weeter M.D. director Weeter Pathological Laboratory Louisville Ky.
Hollis A. Allen M.D. director Clinical Pathological Laboratory St. Louis
I. Warren Jackson M.D. director Laboratory of Clinical Pathology Austin Texas
A. M. Ecklund M.D. director Pathological Laboratory of the Kaula Medical Society Kaula Kauai Hawaiian Islands

Michigan October Examination

Dr F C Warnshuis, secretary of the Board of Registration in Medicine in Michigan, reports the written examination held at Lansing, Oct 14 16, 1930. The examination covered 14 subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-five candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Loyola University School of Medicine	(1930)	80.9	82.3*
Northwestern University Medical School	(1930)	79.7	84.7
Ogden Graduate School of Medicine	(1930)	78	84.4
Rush Medical College	(1930)	79.7	84.7
University of Louisville School of Medicine	(1929)	82.2	85.8
Johns Hopkins University School of Medicine	(1929)	77.8	89.9
Boston University School of Medicine	(1930)	80	83.7
University of Michigan Medical School	(1929)	82.2	83.7
University of Minnesota Medical School	(1930)	82.9	79.6
St. Louis University School of Medicine	(1930)	83.7	80.1
Dalhousie University Faculty of Medicine	(1924)	79.6	78.9
(1928) 77.7 (1929) 82.7			
Queen's University Faculty of Medicine	(1929)	79.7	79.8
University of Alberta Faculty of Medicine	(1930)	77.8	
University of Toronto Faculty of Medicine	(1928)	79.8	
(1929) 79.8 80.9 82.8, (1930) 81.7			

Dr Warnshuis also reports 45 physicians licensed through reciprocity with other states from Aug 6, 1930, to Jan 1, 1931. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine	(1928)	1926	Arkansas
College of Medical Evangelists	(1930)	1929	Tennessee
Howard University School of Medicine	(1929)	1927	Virginia
Chicago College of Medicine and Surgery	(1912)	1926	Illinois
Loyola University School of Medicine	(1930)	1926	Illinois
Northwestern University Medical School	(1929)	1926	Iowa
Rush Medical College	(1926)	1926	Illinois
Univ of Illinois Coll. of Med (1913)	(1913)	1926	Illinois
State University of Iowa College of Med	(1927)	1929	Iowa
University of Kansas School of Med (1911)	(1928)	1929	Kansas
University of Louisville School of Medicine	(1927)	1927	Kentucky
Johns Hopkins University School of Medicine	(1929)	1929	Minnesota
Harvard University Medical School (1926)	Kansas	1924	Minnesota
University of Minnesota Medical School	(1924)	1930	Minnesota
St. Louis University School of Medicine	(1930)	1930	Nebraska
Creighton University School of Medicine	(1926)	1927	Nebraska
University of Nebraska College of Medicine	(1925)	1926	Wisconsin
Albany Medical College	(1926)	1926	New York
University of North Carolina School of Medicine	(1903)	1929	N Carolina
Eclectic Medical College Cincinnati	(1916)	1928	Ohio
Ohio State University College of Medicine	(1916)	1928	Ohio
University of Cincinnati College of Medicine	(1923)	1928	Ohio
Hahnemann Medical College of Philadelphia	(1921)	1927	Penn
Jefferson Medical College	(1927)	1927	Louisiana
University of Pennsylvania School of Medicine	(1913)	1927	Penn
Memphis Hospital Medical College	(1927)	1927	Arkansas
University of Tennessee College of Medicine	(1927)	1927	Tennessee
Medical College of Virginia	(1927)	1927	Virginia
University of Virginia Department of Medicine	(1904)	1930	Virginia

* This applicant has received his M.B. degree and will receive his M.D. degree on completion of one year's internship in a hospital.

Wisconsin September Examination

Dr Robert F Flynn, secretary of the Board of Medical Examiners of Wisconsin, reports the oral written and practical examination held at Milwaukee Sept 10 1930. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. Seven candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Rush Medical College	(1930)	80.9	82.3
Marquette University School of Med	(1930)	80.9	82.3

Dr Flynn also reports 24 physicians licensed by reciprocity with other states at the same meeting and on June 27, 1930. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas School of Medicine	(1928)	1926	Arkansas
University of Georgia Medical Department	(1913)	1929	Georgia
Loyola University School of Medicine	(1930)	1929	Illinois
Northwestern University Medical School	(1929)	1926	Illinois
Rush Medical College	(1926)	1926	Illinois
University of Illinois College of Medicine	(1926)	1926	Illinois

Book Notices

PROTOZOAN PARASITISM OF THE ALIMENTARY TRACT. PATHOLOGY, DIAGNOSIS, TREATMENT. By Kenneth M. Lynch, M.D., Professor of Pathology, Medical College of the State of South Carolina. Cloth. Price \$3.75. Pp. 258 with 57 illustrations. New York: Macmillan Company, 1930.

For years there has been need of a small book dealing in plain terms with the essentials of protozoic parasitism in man. The biologist has long known the species of protozoa infesting the human alimentary tract and has been familiar with their special morphology. Clinicians generally, however, have possessed little accurate knowledge of the subject. Few medical schools have maintained undergraduate or graduate courses dealing with protozoic parasitism; textbooks in common use give meager and vague information (often enough, too, illustrated by archaic drawings) on the topic. The general practitioner still regards protozoic parasitism as "tropical diseases."

Dr Lynch's book attempts to bridge the gap between the biologist and the clinician, and in view of the fact that the doctor is a pathologist and not a practitioner he has done a good job. There are brief but authoritative chapters on the life of protozoa, their dissemination and the prevention of infection, and then chapters containing a fairly complete morphologic, pathologic and clinical consideration of the common protozoa infesting man. The amebas (five chapters), the flagellates (four chapters), and one chapter each devoted to the ciliates, the coccidia and Blastocystis. These chapters are adequately illustrated with photographs of gross material (many original with the author), line drawings from actual material, by Mr J. M. Hicks, and reproductions of pathologic sections. It is informative and refreshing to note that the author has discarded the oft-reproduced and inaccurate pictures of protozoa and their effects which have marred textbooks for years and which date back almost to the age of "hand glass" pathologic observation. It is unfortunate that Dr Lynch has not seen fit to include reproductions of roentgen films ('progress' and 'enema' observations) which recent workers, notably Vallarino, have shown to be so helpful in gauging the damage to the bowel produced by the extraluminal activity of *Endamoeba histolytica*, *Balantidium coli* and the coccidia. It may be that as a pathologist the author has not had opportunity of observing the diagnostic value of roentgenography in this respect.

Of special worth Dr Lynch emphasizes the oft-neglected study of encysted protozoa as a means of accurate recognition of the protozoa; the observation of stained specimens from suited fresh material; the significance of cultures on the newer mediums (it is strange that in the chapter on the ameba the medium of Johns is not discussed), and the necessity for differentiation between pathogenic and nonpathogenic species. Sections on treatment are brief and on the whole in accordance with modern special practice.

In the management of endamebiasis special is not stressed so sufficiently as commonly and the therapeutic line relative to tracing the alimentary tract from the protozoa and the measures requisite for treating the extra-intestinal disseminations of the parasite and the damage that it has done is not so sharply drawn as clinicians would like to see it. It has been well established that it is the extra-enteric spread of such protozoa as *Endamoeba histolytica* and *Balantidium coli* that seriously incapacitates the host and requires the greatest efforts in management. Thymus and colon are not mentioned under the chapters dealing with treatment of the flagellates and ciliates even though they can have the backing of such eminent authorities as Dele and Castellani. There is but scant consideration of diet. Only casual mention (page 189) is made of the occurrence of protozoa in the liver and the biliary tract despite the recent observations made in this country, Korea, Soviet Russia, the French colonies, and South Africa.

The book contains a list of references important to its subject and there are both author and subject indexes.

Dr Lynch is to be congratulated on putting out a compact and authoritative book on a subject which has been hitherto neglected. It is a book which every clinician and biologist should have on his shelf. It is a book which every clinician and biologist should have on his shelf.

HANDBUCH DER NORMALEN UND PATHOLOGISCHEN PHYSIOLOGIE MIT BERÜCKSICHTIGUNG DER EXPERIMENTELLEN PHARMAKOLOGIE. Herausgegeben von A. Bethé, C. v. Bergmann, G. Lindén und A. Illinger. Band IV. Resorption und Excretion. Bearbeitet von A. Adler, Ph. Filling, O. Furrh usw. Paper. Price 99 marks. Pp. 849 with 186 illustrations. Berlin: Julius Springer, 1929.

HANDBUCH DER NORMALEN UND PATHOLOGISCHEN PHYSIOLOGIE MIT BERÜCKSICHTIGUNG DER EXPERIMENTELLEN PHARMAKOLOGIE. Herausgegeben von A. Bethé, C. v. Bergmann, G. Lindén und A. Illinger. Band XIII. Schutz und Angriffseinrichtungen. Reaktionen auf Schädigungen. Bearbeitet von M. Askanazy, R. Dörr, H. Ehrhard usw. Paper. Price 92 marks. Pp. 895 with 75 illustrations. Berlin: Julius Springer, 1929.

HANDBUCH DER NORMALEN UND PATHOLOGISCHEN PHYSIOLOGIE MIT BERÜCKSICHTIGUNG DER EXPERIMENTELLEN PHARMAKOLOGIE. Herausgegeben von A. Bethé, C. v. Bergmann, G. Lindén und A. Illinger. Band XV. I. Hälfte. Correlation I/I. Bewegung und Gleichgewicht. II/I. Physiologie der körperlichen Arbeit. I. Bearbeitet von H. v. Bracken, W. v. Buddenbrock, R. Du Bois Reymond usw. Paper. Price, 86 marks. Pp. 832 with 293 illustrations. Berlin: Julius Springer, 1930.

HANDBUCH DER NORMALEN UND PATHOLOGISCHEN PHYSIOLOGIE MIT BERÜCKSICHTIGUNG DER EXPERIMENTELLEN PHARMAKOLOGIE. Herausgegeben von A. Bethé, C. v. Bergmann, G. Lindén und A. Illinger. Band XVI. I. Hälfte. Correlationen II/I. Physiologie und Pathologie der Hormonorgane. Regulation von Wachstum und Entwicklung. Die Verdauung als Ganzes, die Ernährung des Menschen als Ganzes. Die correlative Funktionen des autonomen Nervensystems. Regulation der Wasser-Ionenkonzentration. Bearbeitet von I. Abelson, G. v. Bergmann, A. Biedl, O. Furrh usw. Paper. Price 121 marks. Pp. 1159 with 245 illustrations. Berlin: Julius Springer, 1930.

Four of the more recently published volumes of this exceedingly useful handbook have just come for review. These four volumes contain alone 1773 pages. It is obvious that a detailed and intensive review is out of the question here. At the best one can only indicate the table of contents of the present volumes and in a general way again call attention of the biomedical profession to the usefulness of this monumental work. The entire set of seventeen volumes is now nearing completion. No progressive modern medical biologic or hospital library can well afford to be without this extremely useful bibliographic and informational tool even if its first cost should seem to be prohibitive. It should be emphasized that this encyclopedic treatise over the range of the physiologic sciences comprises also the pathologic aspects of physiologic phenomena and hence should be found most useful to clinicians particularly since many clinicians of note have contributed important sections to the *Handbuch*.

Volume IV deals with normal intestinal absorption, deviations from the normal, pharmacology of absorption in the gastro intestinal tract, cutaneous absorption, absorption from the peritoneal cavity and other serous sacs, and the comparative physiology of absorption. After a discussion of the physiologic anatomy of the kidney and physical chemistry of the urine, the formation of urine is thoroughly discussed followed by a section on the theories of urinary secretion. Various kidney diseases are discussed. The kidney-like excretory organs of invertebrates completes this section. The remainder of the volume deals with biliary and urinary calculi, the intestine as an excretory organ, feces and excretion by the skin and the liver. Urine expelling mechanisms are thoroughly reviewed from a physiologic and pharmacologic standpoint.

Volume XIII, after discussing weapons of offense and defense among the protozoa and metazoa and the various toxins of animals and their action, devotes several small sections to color changes, pigmentation and autotomy. The greater part of the volume concerns itself with reactions (local and general) to noxious influences of various sorts. An excellent discussion of immune processes and allergic phenomena covers some 400 pages. The remainder of the book deals with phagocytosis and tolerance to poisons. It will thus be seen that this volume is of particular interest to pathologists and immunologists.

In the first 156 pages of volume XV is a consideration of posture equilibrium and movements of mammals, birds, amphibians, reptiles and invertebrates. Walking, running, jumping, swimming and flying are next discussed. There next follow several chapters on disturbances of posture and locomotion in man. This naturally leads to a discussion of vertigo and sea sickness. The remainder of the volume 300 pages is devoted to muscular work under the headings: physiology of work capacity of work in its dependence on the neuromuscular system, psychology of muscular work, permanent effect of strenuous muscular work

on organs (effects of training), and general metabolism of muscular work. This volume should be in the hands of every athletic director interested in the scientific aspects of the profession.

After a brief discussion of the morphology and chemistry of the endocrine glands, volume XVI takes up the various glands of internal secretion (thyroids, parathyroids, thymus, hypophysis, pineal, suprarenals and pancreas). Next comes an excellent discussion of the interrelation of the endocrine glands. The remaining subjects are specified in the title. The section on the parathyroids by Pincus is most inadequate. In fact, it is some six years behind the advances made by American authors.

A complete volume of the handbook can be bought separately.

INDUSTRIAL MICROBIOLOGY. THE UTILIZATION OF BACTERIA YEASTS AND MOLDS IN INDUSTRIAL PROCESSES. By Henry Field Smyth, M.D. Dr. P.H. Assistant Professor of Industrial Hygiene, University of Pennsylvania, and Walter Ford Obold, M.S. Assistant Professor of Biological Science, the Drexel Institute. Cloth. Price, \$6. Pp. 313. Baltimore: Williams & Wilkins Company, 1930.

The part played by bacteria yeasts and molds in the fields of medicine and agriculture is rather widely known. A few of the industrial applications of bacteriology are also matters of common knowledge. Such applications as are found in the manufacture of vinegar and alcohol, the role of bacteria and molds in the manufacture of cheese and the prevention of spoilage by refrigeration are examples. It is not so well known, however, that bacteria are of commercial importance in the production of such chemicals as butyric, citric and oxalic acids and amyl, butyl and isopropyl alcohols. The authors have attempted to get together these and other applications of microbiology to industry. The topics include those indicated and applications to other industries such as the manufacture of glue and of gelatin, tanning, the refining of sugar and the preparation of meats. The disposal of sewage by modern methods of treatment is referred to perhaps more briefly than the subject deserves, since the processes involved are fundamentally microbiologic in nature. Many of the other discussions are brief, but they serve to give the student of microbiology an insight into the more important commercial applications.

LABORATORIUMSTECHNIK UND RÖNTGENVERFAHREN. EIN HANDBUCH FÜR DEN ARZT UND DIE TECHNISCHEN ASSISTENTEN. Herausgegeben von Dr. Walter Justig, Oberreg. u. Obmed. Rat a. Pol. Pras., Berlin. Band I. Das Röntgenverfahren. Ein Lehrbuch für den Arzt und die technische Assistenten. Von Dr. Kurt Kirschmann, Facharzt für Röntgenologie in Berlin. Mit einem Geleitwort von Oberregierungs- und Obmedizinalrat Dr. Walter Justig. Paper. Price 23 marks. Pp. 345 with 283 illustrations. Leipzig: Georg Thieme, 1930.

This book is a complete reference library in itself for the roentgenologist or technician who is able to read German. Every phase of the physics of electricity and of the roentgen rays is discussed thoroughly and briefly. Such phases of the problem as the Quanten theory and the Compton effect, which the technician ordinarily considers complex and difficult, are described in a brief, simple, easily understandable manner. The section on the construction of the roentgen apparatus will be of little value to the user of American made machines, but the theoretical considerations are fundamental and valuable to the reader. An interesting chapter deals with the biologic effect of roentgen rays and radium on various types of tissue. The underlying principles of the various methods and the instruments used, for the measurement of radiation are described. Qualitative and quantitative dosage, depth dosage and cross firing are discussed, and numerous tables and curves are included to assist the reader. A chapter discussing dark room technique is included. An excellent chapter discussing twenty-four artefacts and film defects with directions for preventing these troubles will prove especially valuable for the technician. The chapter on technique is profusely illustrated and includes a discussion of all the apparatus commonly used, such as diaphragms, stereoscopes, immobilization devices and opaque mediums. There is also a series of photographs to illustrate the more common standard positions for examining the various portions of the body. A separate section deals with the technique of roentgen therapy and includes a description of the methods generally used. Methods of approach and protection of the patient are especially stressed. Another interesting chapter deals with the

uses of the roentgen rays in industry. Examination of metals for impurities, and chemical analysis by means of the roentgen rays are described. A brief description of the principles of radium therapy, a few words concerning the attitude of the technician toward the patient, a miniature medical dictionary and a list of the more common terms the technician is likely to meet in his work make this book the most complete in its field. A casual description of the contents of this volume really does not do the author justice. There is perhaps no other work of this type that is as thorough, easy to understand, and as completely illustrated. The book should be in the library of every roentgenologist and technician.

GYNÄKOLOGISCHE OPERATIONSLEHRE. Von Dr. H. v. Pecham, Hofrat o. ö. Professor der Geburtshilfe und Gynäkologie, Vorstand der I. Universitäts-Frauenklinik in Wien, und Dr. J. Amreich, Privatdozent für Geburtshilfe und Gynäkologie an der Universität in Wien. Cloth. Price 140 marks. Pp. 766 with 448 illustrations. Berlin: S. Karger, 1930.

This extensive treatise on operative technic is divided into three parts: (1) operative principles and technic of preparation for operation, (2) surgical anatomy of the female pelvis, and (3) operative indications and details of operative technic. In the first part there is a description of the modern operating room and materials employed, together with numerous illustrations covering fundamental principles. Methods of anesthesia, technical discussion of local, spinal and sacral anesthesia, the details of saline infusion, blood transfusion and the care of complications are excellently presented. Postoperative ileus, postoperative peritonitis and other complications are discussed in detail. Advocacy of surgical intervention as a routine measure in patients with postoperative peritonitis, and frequent recourse to major surgery in patients with serious puerperal infection and in accidental perforation of the uterus are not in accord with accepted American methods. The Vienna school appears to be still impressed with the high morbidity and mortality of puerperal infection, in contrast with American experience that expectant care nearly always yields satisfactory results. The second part is a well prepared and excellently illustrated section. Numerous drawings give in detail, special features of pelvic anatomy with emphasis on those features which are of most interest and importance to the gynecologic surgeon. A study of these charts would be clarifying to any one in need of information relative to the surgical anatomy of the female pelvis. The third portion of the book, concerned with the technic of special operative procedures, comprises two thirds of the volume. The principles and technic of operation for carcinoma of the cervix are well presented. The technic of vaginal hysterectomy and the details of the Litzko operation and the Wertheim technic of abdominal hysterectomy are excellently prepared and are illustrated by numerous drawings accompanied by accurately descriptive legends. This portion of the book is particularly attractive and described with unusual clarity. Other gynecologic operations, such as comprise the surgical work usually encountered in gynecology, are presented nicely. The technic of plastic procedures, while fairly satisfactory, is perhaps not up to the standard of the remainder of the book. On the whole Pecham and Amreich have made a real contribution. Their work is presented in an attractive and original manner. As a reference for the technic of operative gynecology the volume possesses unusual merit.

THE CHEST IN CHILDREN ROENTGENOLOGICALLY CONSIDERED. By F. Gordon Stollhoff, M.D., Assistant in Pediatric (Assistant Radiologist) at Sinai Hospital. Foreword by Bela Schick, M.D., Pediatrician at Sinai Hospital, New York. *Annals of Roentgenology*, Volume VII. Edited by James T. Crue. Cloth. Price \$15. Pp. 432 with 425 illustrations. New York: Paul B. Hoeber, Inc., 1930.

This is the work the pediatrician has long awaited. It is a roentgenologic panorama of chest conditions in children. Every clinical entity receives its roentgenographic replica. The author speaks the clinician's language. A pediatrician is the roentgenographer. The work is divided into sections on the trachea and bronchus, lungs, pleura, mediastinum, diaphragm and chest wall with appropriate and logical subdivision. It is not a glorified atlas. It is more than a description of plates. Rather, subjects are discussed and roentgenographic illustrations offered. One clinician is telling the other and his interpretation records physical conditions with the appearance on the film. There are

constant references to other plates scattered throughout the text testifying to the emphasis placed on differential diagnosis. In complicated situations the author exhibits diagrams. In this way explanations make clear such mysteries as how a given lesion may appear in misleading areas of the lung fields or be entirely lost to view on the plate, depending on the relative positions of tube and patient. The roentgenologically illiterate clinician who can only read a roentgenographer's report will be encouraged to learn that he too may decipher the plate. The roentgenologically puttering clinician will learn to appreciate the fine points and experience a keener zest in his roentgenologic searchings. Too much praise cannot be bestowed for the clarity of the plates and excellence of the format as regards quality of the paper and serviceability of the binding. In a work whose standard is excellence, two comments require registration. There is no section on the heart, which the title might lead the reader to expect. A preliminary section outlining the changes in the general contour and internal structure of the chest from birth to puberty would enhance the value of the material to the layro and complete an already comprehensive and authoritative volume. The development of the chest of the child could be diagrammed simply and illustrated with a few typical roentgenograms.

MEDIZINISCHE PRAXIS. SAMMLUNG FÜR ÄRZTLICHE FORTBILDUNG. Herausgegeben von Prof. Dr. L. R. Grote, Chefarzt der C. von Noorden Klinik, Frankfurt a. M., Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Städtischen Krankenhauses, Dresden-Friedrichstadt, und Prof. Dr. K. Warneke, Direktor der Städtischen Frauenklinik zu Dresden. Band IV. Moderne Pharmakotherapie. Grundzüge der klinischen Arzneimittellehre. Von Professor Dr. I. Lipowski, Chefarzt des Sanatoriums Kurhaus Hubertus, Berlin-Schlachtensee. Paper. Price \$50 marks. Pp. 166. Dresden: Theodor Steinkopff, 1930.

This booklet is intended to help the physician through the perplexing mazes of the newer remedies in a way attempting, to dispose of the problem for the Germans that the Council on Pharmacy and Chemistry is trying to solve for us though in a somewhat different manner, as the author classifies the remedies according to their use and discusses the older remedies that are still being used alongside the newer products. The author points to the remarkable fact that in Germany (just as in this country) an entire floor of a modern medical building is devoted to etiology, another floor to pathologic anatomy and its scientific investigation, another floor to diagnosis and prognosis, and in little room to the Cinderella therapy. Therapeutics must be endowed with special suitable institutes in which therapy in all its phases medicinal as well as nonmedicinal may receive adequate cultivation before a better day in therapeutics can dawn.

HISTORIC ARTIFICIAL LIMBS. By Vittorio Putti, M.D., Professor of Orthopedic Surgery, University of Bologna. Cloth. Price \$150. Pp. 63 with illustrations. New York: Paul B. Hoeber, Inc., 1930.

This book is of interest to the student of artificial limbs and to no one else. It contains a condensed exposition of what is known at present on the subject.

ÉTUDE SUR LES ARCELFÉSSIES. CONSIDÉRATIONS SUR L'APARTEIL RIGIDE LATÉRAL DU SOMMEIL. Par le Dr. Abbe Kyriakopoulos, de la Faculté de médecine de Paris. Paper. Pp. 195. Paris: Norbert Maloine, 1930.

In this doctoral dissertation prepared under the guidance of Professor Lhermitte, the author describes the various types of pathologic sleep. She rejects the notion of essential or idiopathic narcolepsy current in some quarters. In most of the cases that came under her observation a history of cerebral disorder could be demonstrated and she concludes that narcolepsy is symptomatic in nature. The presence, in the region surrounding the third ventricle of a mechanism regulating sleep is indicated both by the location of the lesion in patients suffering from disturbances of sleep and by the results of experimental work on animals. An extended bibliography completes the volume.

PETTITES CLINIQUES (DEUXIÈME SÉRIE). Par Louis P. Boudin, Professeur de Médecine à l'Université de Louvain. Paper. Price 3 francs. Pp. 247. Paris: Masson & Co., 1930.

This collection of clinical lecture is well arranged in the style for which the French clinicians are famous. American student and practitioners however have many excellent sources of similar nature at their disposal in English so that its usefulness to them will be limited.

Medicolegal

Pyogenic Infection an Accident

(*Maryland Casualty Co v Massey* 38 Fed (2d) 774)

Massey was insured by a policy covering death caused, independently and exclusively of all other causes, directly through accidental means. The policy expressly excepted from its benefits bodily injury through bacterial infections, except pyogenic infections which occur simultaneously with and through an accidental cut or wound. The insured plucked a hair from his nose, infection set in, and he died of septicemia. The beneficiary sued the insurer and medical testimony to the following effect was introduced. A hair is embedded in a follicle, the plucking of a hair will leave a tiny orifice in the skin or mucous membrane, which may provide a portal of entry for pyogenic germs into the blood stream or the lymph stream. Staphylococcus germs are usually present on the skin, infection from the plucking of a hair, while not wholly unknown, is very unusual, any injury to the skin or mucous membrane may provide a portal of entry for pyogenic germs, it is difficult for a physician in a given case to determine the exact portal of the entry. Thereupon the court instructed the jury to find for the beneficiary, if the insured died from blood poisoning induced from his pulling a hair from his nose, which caused a wound into which pyogenic germs entered it or about the time the wound was made. The jury so found and the insurance company appealed to the Court of Appeals of Maryland, Sixth Circuit.

Pope v Prudential Insurance Co 29 Fed (2d) 185, said the court, held that there cannot be said to be an accidental cause of any injury when the insured or those acting with his consent did precisely what they intended to do in the way in which they intended knowing that injury often did result and might be unavoidable and when there was no slip or misstep in the performance and no ignorance of any material factor. Whatever may have been the intended character of the insured's act there was a slip or misstep whereby his intended act was, as to the manner of its execution, transformed into an unintended one. If his act produced a wound by tearing or abrading the skin or membrane, certainly such a wound was not intended, and it may be reasonably presumed that infection occurred simultaneously with and through such a wound. There was ample evidence in the record, said the court, to sustain the instruction of the trial court and the finding of the jury. A similar problem was before the court in *U S Mutual Accident Assn v Barry* 131 U S 100, 9 S Ct 755, 33 L Ed 60. There Barry jumped from a platform, after two companions had jumped. They alighted safely, but Barry landed on his feet so heavily as to rupture his duodenum and cause his death. The beneficiary under a policy on his life was awarded judgment on the theory that there was some mishap in the jump, whereby the intended act was in the manner of its performance transformed into an unintended one. The judgment of the lower court was affirmed.

Evidence Chiropractor as an Expert Witness—In a suit based on personal injuries, the defendant objected to a chiropractor's testifying as to the nature and extent of the injuries and expressing an opinion as to their probable duration. He contended that the chiropractor was not shown to be qualified as an expert. It was shown said the United States Circuit Court of Appeals, Eighth Circuit that the chiropractor-witness was a graduate of a school of chiropractic and duly licensed to practice that calling and that the special parts of the body with which the chiropractor deals are the spinal column the spine, and the nerves. The testimony of this witness was restricted substantially to the parts of the body with which his profession deals and to the effect of injuries to such parts on the general health of the injured person. We think said the court that the qualifications of the witness were sufficiently shown and that his testimony did not exceed the limits of his professional knowledge as an expert—*Ellorica, Inc, v Hawkins* 38 Fed (2d) 731.

Medical Practice Acts "License Holder" Defined.—The appellant, by years of practice prior to the passage of the veterinary practice act of Ohio, 1894, was permitted to pursue his calling without taking an examination or obtaining a certificate. In 1925, however, the veterinary practice act was amended and only those were exempted from the obligation to obtain certificates who were "duly licensed" when the new act became operative. It was expressly provided that license holders might continue in practice. The appellant was convicted under the new act, on the theory that he did not have a license. A "license," said the Court of Appeals of Ohio, Cuyahoga County, on appeal is permission conferred by proper authority to pursue a certain trade, profession or calling. The appellant, having been given a legal status by the act of 1894 and permitted to pursue his calling without taking an examination, must be regarded as a "license holder" within the meaning of the act of 1925. He was duly licensed under the laws of the state to practice veterinary medicine and surgery at the time of the act. The judgment of the trial court was therefore reversed—*Staunforth v State (Ohio)*, 170 N E 578.

Workmen's Compensation Acts Injury to Teeth, No Causing Incapacity, Compensable—The general purpose of the workmen's compensation act is to provide compensation for loss of earning capacity resulting from industrial accidents. The scheme of compensation, however, is not necessarily limited to cases in which there is immediate impairment of earning ability. It is within the general purpose of the law, and within the power of the legislature, to provide for compensation for injuries which impair physical efficiency even though the present earning capacity is not directly affected. In most cases, disfigurement or loss of bodily function ultimately impairs earning capacity. Consequently where an employee lost one front tooth and another in an industrial accident he was properly awarded compensation even though the injury did not cause a present disability or incapacity for work—*Amalgamated Sugar Co Industrial Commission (Utah)* 286 Pac 929.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Intravenous Vaccination with Streptococci in Rheumatic Fever—The results obtained by Swift et al up to the present time are not final but are sufficiently favorable to warrant continuation and elaboration of the method. It is especially applicable to two classes of patients (1) those with a continuing low grade infection, (2) those temporarily free from symptoms but in whom relapses may be reasonably expected.

Etiology of Rheumatoid Arthritis—The evidence for the streptococcal origin of rheumatoid arthritis is summarized by Cecil et al as follows: Almost constant presence of streptococci in foci of infection. Streptococci recoverable from blood in 62.3 per cent of rheumatoid patients. 39 per cent in pathologic controls none in healthy controls. Streptococci recoverable from affected joints in 67.3 per cent of rheumatoid patients from blood or joint in 77 per cent none from non

rheumatoid joints. High agglutination of "typical strains" of streptococci with serums of 94 per cent of patients with rheumatoid arthritis. Disappearance of agglutinins with recovery from symptoms of arthritis. Biologic identity of streptococci recovered from blood, joint and focus of infection in the same patient, though there have been a number of exceptions to this rule. Reproduction of rheumatoid arthritis in rabbits with "typical strains of streptococci. Recovery of same streptococci from blood and joints of arthritic rabbits. Striking similarity of histologic changes in rabbits' joints to those in human rheumatoid joints.

Iron in Treatment of Anemia—Data are presented by Mettler and Minot on ten cases of 'secondary' anemia especially associated with a prolonged defective diet or chronic blood loss which responded rapidly and excellently to iron therapy. The response of the bone marrow to iron administered daily first in small doses with an alkaline and then with an acid beefsteak meal and followed by a fourfold to twelvefold increased dose of iron was studied by observing the course taken by the reticulocytes. Responses of reticulocytes occurred following each of the three procedures. The meat was used only as a medium to maintain the upper gastro-intestinal contents at an approximately constant pH and had no demonstrable effect on blood formation. The responses to iron fed with beefsteak at a high pH were usually slightly less than those that followed a few days later from the administration of the same dose of iron with meat at a low pH. Thus it is concluded, particularly because the same dose of iron fed with beefsteak at an acid pH caused a prompt second response of reticulocytes that iron is more potent for blood formation when absorbed from an acid than an alkaline medium within the intestinal tract. The third responses induced by increased doses of iron indicate that the small doses were not optimal and serve to emphasize the importance of optimal doses of iron for patients with anemia that can be benefited by this element.

Epinephrine in Angina Pectoris—In a single instance reported by Cottrell and Wood, subcutaneous injection of 1 cc of 1:1000 epinephrine as a diagnostic test for angina pectoris resulted in a violent attack of substernal pain persisting for over eight hours, in collapse unconsciousness, bradycardia, cessation of respiration and a fall in blood pressure from 170/115 to 80/60 and in electrocardiographic changes suggesting added myocardial damage. Therefore the therapeutic use of epinephrine in patients who may possibly have angina pectoris requires great care. This caution probably applies likewise to ephedrine.

Insulin Shock and Myocardium—Because of the gravity of the changes noted in the presence of myocardial lesions, particular caution is enjoined by Middleton and Oatway in the use of insulin in such patients. Where any question as to myocardial competency exists the avoidance of hypoglycemia must be insured by an adequate coverage of insulin through concomitant intravenous injections of dextrose even though there is no agreement as to the causal relationship of the depressed blood sugar. The practice of inducing insulin shock for whatever purpose is unphysiologic, and in view of possible myocardial injury its occurrence cannot be condoned if avoidable.

Diabetes Mellitus—A series of 1,073 cases of diabetes was analyzed by Wendt and Peck. There were twice as many females as males. The age of obesity was the age of diabetes or arteriosclerosis and of gangrene. Diabetes may develop following excessive nervous and mental strain and this type is usually mild. Familial factors were found in 14.8 per cent, and there is a much higher incidence among the more intelligent class. Syphilis is probably not as uncommon among patients with diabetes as has been supposed. A case of latent syphilis might possibly become activated under good diabetic management. Coma and arteriosclerosis are the chief complications. The former may be eradicated by educational measures plus insulin. The latter remains as the toughest problem and is the cause of the rising death rate from diabetes. Insulin is necessary for about one third of diabetic patients and must be used temporarily or another third, while the remainder can get along without it. Large doses are usually not necessary. Dextrose is not necessary in the treatment of most cases of coma. The cholesterol determination has been of value in following the progress of cases. A more nearly

constant blood sugar level may be obtained in some patients by feeding them every eight hours, and less insulin is used by so doing. The mortality rate is still rising. Arteriosclerosis is now the greatest problem in diabetic management.

Thyroidectomy for Thyrotoxicosis in Older People—A consecutive series of 200 cases of thyrotoxicosis is reported by Mora and Greene for which thyroidectomy had been performed on patients varying in age from 50 to 76 years. These formed 18.8 per cent of a consecutive series of 1,060 patients. The proportion of females to males was 2.5 to 1, 66.5 per cent of the cases were primary hyperplastic thyroids, the remainder were nodular goiters. The average duration of goiter was 11.68 years, the average duration of symptoms was 23.2 months, the average interval between the appearance of the goiter and that of symptoms was 14.5 years. The principal symptoms in this series were weight loss, tachycardia, nervousness, tremor, weakness, palpitation and exophthalmos, in the order given. There were thirty cases of preoperative auricular fibrillation, in twenty-seven of which normal rhythm was restored. Sixty-one cases exhibited exophthalmos. All but five returned to normal. The average preoperative basal metabolic rate was 41.6 per cent above normal, the average postoperative rate was 1.1. All of the cases, whether of the hyperplastic or the adenomatous type, showed a definite response to iodine therapy preoperatively. Of 175 patients on whom accurate postoperative data are available, 171 were completely relieved of their thyrotoxicosis, as measured by a fall to normal of the basal metabolic rate. There were 6 operative deaths in this series of 200 cases. The total mortality (7 deaths) of the entire series of 1,060 cases, which formed the basis of this report, was 0.66 per cent.

Brucella Infection—A case is described by Lervell and Amoss in which *Brucella* was recovered from the bile removed by duodenal drainage and from the gallbladder contents at operation. In a patient whose extirpated gallbladder contained *Brucella*, the stools, from which *Brucella* was isolated prior to operation, no longer showed these organisms following cholecystectomy.

Human Intestinal Protozoa—In 522 cases studied by Andrews and Paulson the total incidence of human protozoa infesting the intestinal tract was 10.9 per cent. By species: *Endameba histolytica*, 0.2 per cent, *Endameba coli*, 4.2 per cent, *Endolimax nana*, 2.5 per cent, *Iodameba williamsi*, 1.3 per cent, *Trichomonas hominis*, 2.1 per cent, *Chilomastix mesnili*, 1.3 per cent, *Giardia lamblia*, 2.7 per cent, *Embadomonas intestinalis*, 0.2 per cent.

Cinchophen Poisoning—Fifteen cases of fatal cinchophen poisoning have been recorded, including four reported by Parsons and Harding. Striking pathologic changes in the liver have been found in all of the fatal cases studied at necropsy. The total amount of the drug taken in these cases has varied from 37½ to 7,050 grains (25 to 456 Gm). Intensive dosage with cinchophen may produce acute hepatic degeneration. Long continued administration of the drug in moderate doses may result in subacute and chronic hepatic degeneration.

Ganglioneuroma of Retroperitoneal Origin J McFarland Philadelphia—p 118

Fetal Adenoma of Hypophysis and Dermoid Cyst of Hypothalamus—A fetal cell adenoma of the hypophysis and dermoid cyst of the hypothalamus are reported by Shapiro. The first tumor resembled one of the so called pars intermedia tumors. It originated, however, not from a pars intermedia but from the midportion of the pars anterior. It was composed not of the specific differentiated pars intermedia cells but of undifferentiated fetal cells. If man has a pars intermedia comparable with that of lower animals, it is rudimentary, variable and functionless. There is no histologic proof as yet establishing its presence. The dermoid cyst belonged to the group of inclusion tumors of the hypophyseal area. It was derived from embryonal rests of cranial external ectoderm included during the invagination of the brain vesicles. It was related to Erdheim's tumors derived from rests of oral ecto-

dorm inaugurated with Rathke's hypophyseal pouch. It involved the hypothalamus, leaving the hypophysis relatively intact, and yet produced the diabetes insipidus and the diabetes mellitus usually ascribed to hypophyseal lesions. The diencephalon rather than the hypophysis is chiefly responsible for these syndromes.

Syphilitic Coronary Arteritis—In six of the eight cases studied by Moritz, the stenosis of the coronary arteries was due to or contributed to by syphilitic arteritis of their proximal portions. In none of these did the arteritis extend farther than the first 10 to 12 mm of the vessel. In some, the stenosis was at the orifice, while in others the orifice was patent and the stenosis was distal to the aorta. Active syphilitic coronary arteritis was present with chronic inflammation of the aorta and in some cases the coronary disease was chronic while the aortic syphilis was active. The coronary disease was not in all cases associated with syphilitic aortic valvulitis. The course of the coronary arteritis as hypothesized from a comparison of the mild with the severe pathologic changes indicated that the vascular change began in the adventitia as an obliterative endarteritis with perivascular infiltration of lymphocytes and plasma cells and medial damage, progressing from the periphery in toward the lumen of the vessel. Some of the arteries with these mild changes were stenosed at their orifices by proliferation of the aortic intima. In cases in which the proximal extra aortic portion of the coronaries was stenosed the stenosis was due to intimal proliferation. In some instances the proliferated intima had the appearance of well vascularized granulation tissue infiltrated by lymphocytes and the media was disrupted by exudative, vascularized granulation tissue with considerable thickening of the adventitia. The end stage of this coronary endarteritis was thrombosis of the narrowed lumen with organization and in some instances, calcification of the obliterating thrombus. In three cases, immediate cause of death appeared to be an obliterative coronary arteritis. All three patients died following sudden cardiovascular collapse characterized clinically as coronary disease. Two of these three had preceding anginal attacks. Electrocardiographic studies were not significant so far as coronary disease was concerned and histologic studies of the myocardium failed to disclose evidence of infarction. It seems probable that in two of these cases there had developed a collateral circulation which by exclusion must have been either through the thebesian or through the aortic periadventitial vessels. The latter was deemed improbable because no periadventitial vessels of sufficient caliber to supply the heart were found in the ascending arch. In both of these there was almost complete obliteration of both coronary ostia, and this obliteration as judged from the histologic study, was of considerable duration. The reason for the failure of this compensatory circulation after its apparent functional competence was not disclosed. In the third case the syphilitic inflammation was active with military gummas and excessive proliferation of granulation tissue so that it seems possible for the obliteration of this vessel to have been an acute phenomenon. Certain observations made were considered to indicate the patency of coronary thebesian communications.

Scholastic Aptitude Tests for Medical Students—From Moss's report it appears that aptitude tests furnish a useful criterion for predicting success in the medical school. It seems further that better results can be obtained by a combination of test results with other criteria for selecting students especially with premedical grades. He says that no one criterion gives a perfect prediction and only prolonged experimentation will show what is the most reliable combination of criteria. The predictive value of personal interview ratings does not seem to be very high but this factor should be studied further in a larger number of schools and under better controlled conditions.

Vaccines in Chronic Arthritis and Certain Skin Diseases—Strietmann records his experiences with fecal vaccines employed according to Wherry's method. In addition to four dermatologic cases reported, there was an intractable recurring pityriasis which is now free for three years, a chronically recurring angioneuroedema of long standing has now gone over a much longer time than ever before without recurrence four months, a case of exfoliative dermatitis which has recurred for the fourth time. All skin cases had either been tested for food allergies and diet found ineffective, or food allergies had been entirely ignored.

Determination of Erythrocyte Measurements—Blood films have been examined by Cheney with Eves hemometer in 100 cases in which there was no evidence of any abnormal condition of the blood. He found that the hemometer measures the mean diameter of erythrocytes accurately enough to meet all practical purposes. The determination of the average size of the red blood cells is essential to the investigation of a case of Addison's anemia, as a marked macrocytosis may in itself be diagnostic of the condition. A study of the morphology of the erythrocytes is important in the diagnosis and treatment of many disorders of the hematopoietic system. He feels that the facility with which the hemometer can be used should stimulate a more general study of erythrocyte morphology and bring a better understanding of this important subject into the general practice of medicine.

Effect of Electrical Shock on Brains—Sublethal electrical shocks were administered by Morrison et al by occiput and nose contact to laboratory animals, and the brains were subsequently removed and studied histologically with the aim of ascertaining whether electricity produced lesions in the nervous system and if so the nature of the lesions. It was found that lesions were produced in the brain sometimes even after a single shock the nature of the lesions depended, at least to some extent on the nature of the current similar wave forms producing more or less similar lesions. There were some overlapping types of lesions such as hemorrhage, which could be found in all cases and shrinkage of ganglion cells which could be found in three classes of cases but in general the various combinations of lesions were characteristic of the effects of different types of current. Nearly all the structures in the brain were involved in these pathologic processes. The ganglion cells were swollen under some circumstances and shrunken under others. The myelin was affected chiefly in cases in which the gliar proliferated and the nerve cells were swollen. In practically all cases there was congestion and hemorrhage. Edema of the brain was a common finding and, in conjunction with the swelling of oligodendroglia and the production of mucocytic or galactohypid degeneration presented interesting vacuolar lesions. In an attempt to explain the mechanism of the production of these lesions, the heat generated in the brain under most vigorous electrical strain was measured it was found to be relatively insignificant as long as the blood circulation was maintained but it increased rapidly when the circulation was stopped. Furthermore by means of the special technic devised by Forbes, the vessels on the surface of the brain were observed during electrical shock and it was found that they constricted or dilated during the passage of the current depending on the kind of current used. The condenser discharge and induction coil currents caused the vessels to dilate and the intracranial pressure to rise, histologically, one of the most characteristic lesions from these types of current consisted in swelling liquefaction and vacuolization of the ganglion cells. The alternating current, on the other hand brought about a constriction of the peripheral vessels a slowing of the blood flow and histologically a pronounced shrinkage of the ganglion cells. Attention is directed to the coincidence of vascular response with type of tissue change.

Myelitis Compression Caused by Osseous Deposits in Arachnoidea of Spinal Cord—The four cases reported by Puusepp show that one must take into consideration that arachnoiditis ossificans can cause a compression of the spinal cord as well as a tumor or a meningitis circumscripta. At present injections of iodized oil performed according to Sequester's method are helpful in diagnosing similar diseases. As to the character of the process itself, in the first two cases there were typical osseous growths causing a compression of the spinal cord in the third case one may suppose that it was

the first stage, when the bony plates, having accumulated in one area caused an interruption in the flow of the cerebrospinal fluid provoking at the same time an inflammatory process similar to a meningitis circumscripta. This explanation is justified by the fact that in the second case a local accumulation of yellowish fluid was found at once with the osseous growth. The fourth case shows also the presence of a non typical tumor. Thus there is the possibility of various combinations, when either the plate itself grows to such an extent that it provokes a compression of the spinal cord or there is an accumulation of fluid a part of the growth may also have already completed its ossification, whereas the consistency of the second part is that of connective tissue. In these cases there is sufficient evidence to conclude that the pains in the roots that coexisted with the tumors could be provoked by a compression caused by the plates and besides, that the changes in the spinal cord found by many authors during the necropsy must be attributed to local compression of the spinal cord but not to general causes. The changes in the spinal cord found in the second case are characteristic of its changes caused by a compression.

Degeneration of Spinal Cord with Changes in Anterior Horns of Cervicodorsal Region—A case is reported by Stone which from a clinical standpoint was diagnosed as a subacute combined degeneration of the spinal cord. There was clinical evidence of wasting of the small hand muscles in explanation of which cellular changes as axonal retraction in the anterior horns of the cervicodorsal regions were found. Multiple hemorrhages were not found. Also no evidence of inflammatory reaction either in the leptomeninges or in the parenchyma of the spinal cord were found. The gray matter involvement was entirely separated from that of the white matter. In the dorsal and lateral aspect the white matter directly adjacent to the gray matter was normal. The clinical pathologic evidence seen is not sufficient to conclude an additional separate disease.

Bovine Tubercle Bacilli in Man—Twenty-five strains of tubercle bacilli isolated from tuberculous lesions in twenty-two children and three adults were typed by Ryan and Voldrich who used the traditional criteria type of growth, acid production, and pathogenicity for rabbits. Although all the strains were recovered from the type of lesions in which the incidence of bovine bacilli is usually high none of the twenty-five strains were found to be typical bovine bacilli.

Blood Cholesterol Values in Hyperthyroidism and Hypothyroidism—Cholesterol values on seventy patients with thyroid disturbances are reported by Mason et al. Hyperthyroid conditions tend to diminish the level of the cholesterol in the blood. The lowest values are found in extremely toxic patients. There is however no definite correlation between the cholesterol value and the basal metabolic rate. True myxedema is accompanied by a marked elevated blood cholesterol. Low metabolic rates however, without clinical evidence of myxedema are accompanied by normal cholesterol values. Cholesterol values are a definite help in estimating the gravity of hyperthyroidism. Cholesterol values are important aids in diagnosis and prognosis and in estimation of response to treatment in patients with hypothyroidism. Possible coincident effects of disordered cholesterol metabolism are suggested.

Dilution and Concentration Test of Renal Function—The dilution and concentration test of kidney function has been performed by Buck and Proger in a hundred patients and compared with other tests of renal function. The advantages of the dilution and concentration test are its sensitivity, its ease of performance, no special laboratory equipment or technical ability being required, its adaptation to the ambulatory patient, and the possibility of its combination with other tests if necessary.

Osteomyelitis in Infant—A case of extensive osteomyelitis involving the left humerus in a girl baby aged 5 weeks is reported by Rice and Corliss. The condition followed multiple abscesses in the lactating breast of the infant. Operation was followed in less than twenty-four hours by death.

Routine Bacterial Examinations in Laparotomies—Leavitt recommends that cultures be taken in all cases in which there is free fluid in the abdominal cavity. Occasionally important information will thereby be obtained and the burden of the cause of death will be placed where it belongs. What is a simple routine may be the means of satisfactorily explaining to relatives and friends a situation that has often been the cause of criticism. It may relieve the surgeon of responsibility for an unfavorable result.

Meningococcemia for Eight Months Following Meningitis—A case of meningococcal septicemia of an unusual type following acute meningitis is reported by Lemann and Tersley. Recovery followed the use of autogenous vaccines but their value is uncertain. Of great importance is the fact that a brother and a sister of the patient had died of meningitis respectively fifteen and six years previously.

Influenzal Meningitis Is Amenable to Treatment—The records of 302 cases have been reviewed by Bloom including ten cases that he observed. All literature published in the United States and some in foreign countries up to March, 1930, is reviewed. The mortality in 302 cases was 92.05 per cent. Seven additional cases of recovery are added to the table of Rivers (1922), including one by the author. Influenzal meningitis is a disease of infancy, as statistics prove. The relationship between the seasonal and the yearly incidence of influenzal meningitis and of epidemic influenza and pneumonia do not coincide, though this series occurred somewhat later than that reported by others. The report of a case treated with human convalescent blood serum, with recovery and no aftermath, should be an inspiration for further study and continued usage.

Celiac Disease Treated with Dennett's Diet—Berney has treated four cases with Dennett's diet of fat free butter, milk and baked potatoes and arrowroot in rather enormous quantities. One patient aged 9 months, weighing 11 pounds (5 kg), with a history of recurrent diarrhea during the past six months and a loss of weight, had been fed on condensed milk since birth and during the past three months had been given soups and crackers. His appetite was poor. The stools were typical of intestinal decomposition. The abdomen was slightly distended and the diagnosis of intestinal decomposition was made. The usual diet for this condition was ordered. Three months later the child now being 1 year old and weighing 12 pounds 14 ounces (5.8 Kg), the clinical picture had changed. The abdomen was enormously distended. The liver and spleen were not palpated there was no movable dullness. The superficial glands were not enlarged the reflexes were normal. The stools were frequent and voluminous, from four to six a day. They were frothy gray, with a somewhat greasy appearance. Pirquet and Mantoux tests were negative and the hemoglobin was 65 per cent. Marked dilatation of the transverse and descending colon was evident from roentgen examination. The patient had been on protein milk for three weeks and been given five intraperitoneal injections of 100 cc of citrated blood, without any apparent change in his condition. He was given eight feedings daily of 8 ounces each of fat free buttermilk. Two days later he was given 8 ounces of buttermilk every two hours, or 96 ounces in the twenty-four hours. Some days, not being satisfied, he was given as much as 112 ounces. This was continued for sixteen days by which time the stools were two or three a day, rather small and well formed, the abdominal distention was less marked and the disposition was improved. He gained 7½ ounces in this period and was standing up in bed for the first time. Then half of a baked potato was given twice a day, which was increased to a whole potato twice a day, the following day and gradually increased until three weeks later he was getting fourteen baked potatoes daily, at which time buttermilk was reduced to 64 ounces a day and later to 48 ounces. The potatoes were steadily increased until he was taking eagerly thirty five potatoes a day (by weight 8 pounds 4 ounces), practically a bushel of potatoes in one week, and having two or three normal stools daily. In this period of less than three months he gained 4 pounds and started to walk, the muscle turgor being much improved.

Mortality Among Nonleper Children in Culion Leper Colony—The morbidity and mortality among the children of lepers born in the Culion Leper Colony have been studied by De Vera with the main object of determining whether or not

the improved general and medical care of the lepers consequent on the intensification of antileprosy treatment, which began in 1922, and the giving of artificial feeding to most of the newborn babies since 1928 have had an appreciable influence on the health of these children. From 1922 to 1926 the commonest causes of illness among the children in the colony, according to the order of frequency, were respiratory disorders, leprosy, gastro-intestinal disturbances, beriberi, malnutrition, skin diseases, congenital debility and tuberculosis. In the last three years, gastro-intestinal disturbances, respiratory disorders, skin diseases, beriberi, malnutrition, tuberculosis, influenza and malaria were the commonest causes of illness in the order mentioned. In the nursery the most frequent complaints for the period from 1922 to 1926 were skin diseases, influenza, gastro-intestinal disturbances, measles, respiratory disorders, dengue(?), varicella, leprosy and tuberculosis. From 1927 to 1929 the order of frequency of the commonest complaints was gastro-intestinal disturbances, skin diseases, respiratory disorders, influenza, malnutrition, conjunctivitis, malaria and otitis media. Aside from leprosy and the absence of specific water and filth borne diseases the causes of illness were what might be expected among children living in nonleper communities in the Philippines. The incidence of leprosy among both colony and nursery children was much higher during the period from 1922 to 1926 than from 1927 to 1929 this was due to the fact that during the former period many of the children had been exposed to infection for several years while since 1927 the children have regularly been removed from contact with their parents at a progressively younger age. Since 1928 no new cases have been reported among the children born in the colony. Cases of malnutrition have apparently become more frequent, especially in the last two years, coinciding with and probably due to the giving of artificial feeding with sweetened condensed milk to most of the new born infants. There has been a slight lowering of the incidence of congenital debility since the intensification of leprosy treatment. The marked lowering of the infant mortality since the intensification of antileprosy treatment has probably been due to improved medical and general care of the lepers and their children. From 1906 to 1921 the chief causes of death in the order of their importance were congenital debility (including malnutrition and premature birth), gastro-intestinal disturbances (diarrhea and enteritis), infantile convulsions, the pneumonias and infantile beriberi. From 1922 to 1929 the order of importance of the chief causes of death was gastro-intestinal disturbances, bronchopneumonia, tuberculosis, infantile beriberi, congenital debility and malnutrition.

Leprosy Treatment at Culion Leper Colony—The results of leprosy treatment at Culion as reported by Lara presented in the foregoing account, should suffice to demonstrate that a large proportion of advanced cases can be and have been successfully treated.

Lapnus—Dychitan states that lapnus is a local term for a disease prevalent in the province of Mindoro heretofore diagnosed as malaria with eczema. It means the peeling of the skin similar to that which occurs after an incident of burning. This external sign characterizes the disease and it is manifested in all those who suffer from it hence it can be considered the pathognomonic sign of the disease. The disease prevails during March, April, May, June, July and August and disappears in September these months coincide with the period at which the rice called *tipucay garangan* has already been stored for several months without previous drying because the rains precluded its exposure to sun and the places are low and damp. Dychitan believes that the rice *tipucay garangan* improperly dried, is the main cause of the disease a predisposing cause is poverty which does not permit the use of other kinds of food and so favors the production of the disease. Hygiene and sanitation do not seem to be factors in the production of the disease. The fact that those who did not contract the disease are those who had the good fortune to sell their cereals and therefore were able to live in that year without being exposed to its ravages further confirms its metabolic or nutritional origin. The disease is not influenced by age or sex. The mortality is from 50 to 60 per cent approximately. Dychitan is inclined to believe that lapnus is a disease similar to the European pellagra. The treatment he used consisted in the administration of saline purgative intestinal disinfectants sea

water with lemon juice and solution of potassium arsenite. It was effective. The sense of smell was normal in all the patients. Vision was defective when opacity of the cornea was present. The movement of both eyes was normal. The sense of feeling was normal. Locomotion was normal so long as there was no lesion on the soles of the feet as a result of the peeling of the skin, which began at the tip of the feet. There was slight deafness, otherwise the sense of hearing was normal. The mental condition was slow. Melancholia was manifested in advanced cases but without signs of illusion or hallucination. Of great importance was the symmetrical appearance of the lesions. Alopecia is also a common symptom among the patients. The hair falls out gradually, to complete baldness.

Leptospira Ictero-haemorrhagiae—Several thousand rats are examined monthly at the federal laboratory, San Francisco. *Leptospira* was found by dark-field examination by Ridlon in the kidneys of seventeen rats, or about one third of the total. These organisms apparently conform to the descriptions of *Leptospira ictero-haemorrhagiae*. Guinea pigs were inoculated with material from the kidneys of rats harboring *Leptospira* and died, showing fever and jaundice of the eyes and skin before death. At necropsy they showed subcutaneous jaundice and hemorrhages of subcutaneous tissues and internal organs, which are the gross pathologic changes described by several writers as typical of infection with *Leptospira ictero-haemorrhagiae*. *Leptospira* was found in the internal organs and urine of infected guinea pigs. Positive cultures were obtained. Guinea-pigs were infected by injection of positive cultures. The disease was carried over in successive guinea pig inoculations, both from original rat injections and from culture injections.

Indigestion That is Best Treated Medically—Alvarez states that the wise physician will not advise operation on all the patients with indigestion who appear to have functional troubles or who have signs of mucous colitis or who have been operated on several times before or who have only recent signs of organic disease or who have not been studied carefully. He will avoid operations on patients with migration of the c

who are psychopathic or constitutionally inadequate to the strain of life, and on those who are worn out with overwork, insomnia, or worry. He will not always advise operations even when he knows that the patient has gallstones or duodenal ulcer but will try to pick out only those patients who are likely to be benefited by the work. The finest thing that can be said of a surgeon is that he operates not to remove a lesion but to restore the patient to health. The finest things that can be said of a gastroenterologist are that he does not hang on indefinitely to patients who should be in the surgeon's hands and that he does not call in a surgeon solely to save himself from diagnostic labor.

Thyroid in Gynecic Practice Menorrhagia—Cooke asserts that menorrhagia, sterility and abortion (separately or in combination) occur as symptoms in certain cases of hypothyroidism. A considerable percentage of these symptoms are apparently relieved by the administration of thyroid, and by no other as yet discovered means. The administration of thyroid in such cases does no harm especially (although not necessarily) when regulated by observations of the basal metabolic rate.

Human Ovary at Laparotomy—Five human ova were recovered by Allen et al from the uterine tubes and definitely identified. Ovulation time in these cases occurred on or one or two days before the fourteenth day following the onset of the previous menses. One mature ovum was recovered from a 10 mm follicle on the fourteenth day of the cycle. The pre-ovulation size of the human follicle may be at least 10 mm in diameter. The human ovum forms the first polar body and the second maturation spindle before ovulation and remains in this stage after ovulation unless fertilized. A majority of the large follicles visible on the surface of the ovary (although apparently normal) prove on examination of the enclosed ovum to be atretic. Considerable amounts of follicular hormone (theelin, 'estrim', folliculin) can be demonstrated by injections and implants into test animals of fresh tissue from both follicles and recent corpora lutea. Corpora lutea of the first few months of pregnancy contain considerable amounts. Corpora of full term pregnancy contain little or none of this hormone, which is, however, abundant in the placenta.

Acute Indigestion in Middle Aged—Nesbit says that the family physician in the general practitioner is the really important member of the medical profession. The family physician sees the patient first. In ninety-nine out of a hundred cases the patient will do what his family physician advises. Let the family physician insist that his patients in the fifth and sixth decades come to him at least once a year for a general physical survey. If he finds some condition requiring further study for which he is not prepared by lack of time or equipment, let him call in the internist. The internist should be glad to work with the family physician in such a way as not to stand in the light between the physician and his patient. The surgeon will profit by not having suddenly without warning, to operate in a some what atypical upper abdominal condition only to find no intra-abdominal disease, and to have an unexplained death on the operating table or a few days later.

Repair of Hernia with Fascial Sutures—McCracken reports on approximately 400 fascial repairs for hernia which he says seem indicated in the following types of cases: (1) direct inguinal hernia, (2) oblique inguinal hernia with a sagging posterior wall in patients past middle age, (3) femoral hernia in which the suture is used to close the entrance of the femoral ring through the inguinal incision, (4) all recurrent hernias and (5) all ventral hernias including umbilical and epigastric. The sutures are taken from the fascia lata of the thigh, each being one fourth inch wide and as long as the particular thigh will allow. They are threaded on a special needle and used as ordinary sutures in doing the plastic repair. One direct hernia recurred at the end of one year, in one case of double recurrent hernia there was recurrence on one side fifteen months after operation.

Extra-Uterine Abdominal Pregnancy Delivery of Living Baby—In the case reported by Bunkley and Brindley there were several interesting points. There was no bloody discharge at any time during pregnancy, the condition of the mother was excellent generally. She was apparently in perfect health with all organs functioning properly, the baby was in perfect condition weighing over 9 pounds and apparently normal in every way, the mother recovered rapidly, leaving the hospital in seven teen days feeling fine and the wound entirely healed. The mother and baby were both doing nicely seven months later, and the baby was developing normally.

Atelectasis—Ten cases are described by Korol three of aortic aneurysm, two of mediastinal tumor, two of leukemia two of Hodgkin's disease involving the mediastinal or hilar glands, and one of postoperative massive atelectasis. In certain cases treated by roentgen rays or radium, the signs of atelectasis disappeared, following a diminution of the size of the mediastinal masses. A short review of the literature indicates that aneurysm and mediastinal tumor have been recognized as causes of atelectasis, but there are no references in the literature to atelectasis accompanying Hodgkin's disease and leukemia. The occurrence of bronchiectasis in atelectasis is discussed including the symptom complex resulting from interference with bronchial drainage.

Sodium Amytal as General Anesthetic—Thompson is of the opinion that sodium amytal should be seriously considered as an anesthetic in certain types of patients coming to United States veterans hospitals for treatment.

Malaria Treatment of Neurosyphilis—All nine cases reported by Robertson have shown a marked mental improvement following malarial therapy. Some of the patients are earning a living at former occupations; others are working at occupations of a simpler character and all have made a fair social adjustment. In those cases in which a spinal fluid examination was made at conclusion of the treatment a distinct improvement of the condition observed before treatment was noted. The greatest improvement in cerebrospinal fluid was observed in the colloidal gold reaction and in the cell count. There seemed to be little change in globulin or in the spinal fluid Wassermann reaction. There was no change in the blood Wassermann tests. The speech defect in some cases seemed to improve. There appeared to be the greatest improvement in the manic type of patient. It is thought that malarial therapy is justified because of its simplicity of technique, the fact that it is easily controlled, its relative harmlessness, and the fact that it produces the greatest percentage of improvement in cases of dementia paralytica.

Prognosis in Mental Diseases Extramural Social Adjustment—Podall reviews some of the common forms of mental diseases in reference to the social and economic adjustment of patients suffering from them. The constitutional psychopath due to abnormal make up usually makes a poor adjustment. The dementia praecox (catatonic form) patient on account of having prolonged remission periods without mental deterioration has more likelihood of social adjustment than one with the hebephrenic form which is characterized by progressive mental deterioration usually necessitating hospitalization. During the periods of remission in the manic-depressive group many individuals are able to be employed; others on account of frequent recurrent attacks are indefinitely hospitalized. Patients with dementia paralytica who received

malarial treatment showed varying results as regards social adjustment. There was a marked physical and mental improvement in a number. Some were at home and employed, while others were unemployed, again, there were patients who remained in the hospital, showing no mental improvement. While the malarial treatment does not cure dementia paralytica, he believes that better results will be obtained after the public at large has been sufficiently educated as to the importance of early and prolonged treatment for any form of mental disease, especially in dementia paralytica and that it is for the best interest of these patients to remain in the hospital until such time as they can be discharged as improved and not against medical advice. He emphasizes the importance of cooperation between the patient, relatives, social service and the medical profession not only in cases of dementia paralytica but in all other forms of mental diseases.

Retinal Arteriosclerosis, Without General Arteriosclerosis in Cases Diagnosticated General Arteriosclerosis—Ballou discusses the striking frequency of retinal arteriosclerosis occurring incidental to cerebral arteriosclerosis especially as compared with generalized arteriosclerosis and other peripheral forms of arteriosclerosis.

Subarachnoid Lavage and Ethylhydrocupreine in Meningitis—This drug is recommended by Mella. The preparation of choice in meningitis should be the hydrochloride to be used in solution for irrigating the subarachnoid space, but the reason for not following that procedure in this case has been stated. It is believed though that, by administering the base early in the progress of the disease and following this with the removal of spinal fluid at regular intervals, satisfactory results may be obtained. The hydrochloride must never be given by mouth and the base should not be used in the subarachnoid space. The drug should not be given for more than three days. A glass of milk should be given with each dose and no other food or medication must be given by mouth during the time covered by this treatment. If it is necessary to appease the appetite more milk may be given but no other food. Puncture of the cisterna magna should not be attempted except by those who have been instructed in the technique and should certainly not be attempted by any one believing that this technique can be acquired by simply reviewing the literature on the subject. However, when the technique is once acquired it will be found to be a great aid in the diagnosis and treatment of many different disorders of the central nervous system.

Liver Feeding in Osteitis Fibrosa Cystica and in Organic Neurologic Conditions—Osteitis fibrosa cystica is a bone disease which has received benefit in one case cited by Wilkinson by a purely dietetic treatment with liver which may be carried on at home as well as in the hospital. He urges that liver therapy should be given an exhaustive trial in all cases of organic neurologic conditions and in those conditions which show decalcification of bone. It is not known what the action of liver diet is but from the results clinically obtained and from laboratory examination it has a beneficial effect on such conditions.

Methylated Antigen in Treatment of Tuberculosis—Forty-eight patients in varying stages of advanced tuberculosis were treated by Evans and Spray with the methylated antigen of Negre and Boquet adhering to the directions of preparation and routine administration as closely as possible. While the early results were somewhat suggestive, later developments failed to reveal any permanent beneficial response to one complete series of thirty-two injections. The procedure was applied elsewhere to forty guinea pigs and to seven monkeys, with no demonstrable results.

ditions A Isle Punch—p 18
- *Symptomless Spontaneous Pneumothorax J R Beal—p 21

Vernes Resorcinol Test in Tuberculosis—On the basis of the results they obtained with the Vernes resorcinol test in twenty-eight cases of extrapulmonary tuberculosis and thirty-six cases of pulmonary tuberculosis Lobban and Smith state that the test cannot be regarded as specific for tuberculosis. In the sixty-four cases the serial tests corresponded with the clinical course of the disease in fifty nine, and hence a progressive decline in the figures obtained was found to be of good prognostic value. The serums from healed cases of tuberculosis whether pulmonary or nonpulmonary show readings below 30 and a Vernes reading below 30 is a good measure of the activity of the lesion. Nonpulmonary cases of tuberculosis generally show Vernes readings below those obtained in pulmonary cases. In cases of bone disease in which there is extensive destruction of the tissue the readings are, however, fairly high. The results obtained in cases of scarlet fever and diphtheria indicate that the amount of flocculation obtained varies with the stage and degree of severity of the illness.

Symptomless Spontaneous Pneumothorax—Beal records a series of six cases of symptomless spontaneous pneumothorax that have come under his notice. In none of the six cases under review was there a history of any exertion or sudden strain and the lesion was discovered in the course of the routine examination of patients known to have pulmonary tuberculosis. In none was there elicited a history of pain in the chest or dyspnea the patients being unaware that anything untoward had happened. In five cases the percussion note was impaired over the area of the pneumothorax, this being due to pleural thickening and adherent pleura. In one case the note was hyperresonant and the breath sounds were absent, but in the remaining cases breath sounds were of a soft, distant, amphoric type. Metallic rales were present in four cases. Fluid was present in three cases giving rise to a definite splash. Fluid was withdrawn in one case and on bacteriologic examination tubercle bacilli were found. Cardiac displacement occurred in two cases on the opposite side to the pneumothorax, but this was only about

1 inch from the normal position. The diagnosis of spontaneous pneumothorax was confirmed roentgenologically in five cases the other patient being too ill for the examination.

- Seasickness M Flack—p 176
- Ketosis in Seasickness J R Marrack—p 178

Subphrenic Abscess—A review of the causes, symptoms and diagnosis of subphrenic abscess is given by Doherty and Rowlands. The treatment is discussed and the posterior sub-pleural method of approach is advocated in order to avoid pulmonary complications. Cases are cited illustrating the complications following the transpleural route. Two of the cases show the advantages of the subpleural route.

Seasickness and Labyrinthine Theory—Matland states that his presentation of the subject of seasickness is not intended to be destructive of all existing remedies. It is rather directed against the assumption that any drug or method of treatment is infallible and is incidentally intended to impress on the ship surgeon the need for careful appraisal of type and when prophylaxis fails analysis and evaluation of signs and symptoms. Only after this can he avoid drugs and methods that are definitely contraindicated. Intervention is sometimes unwise and seasickness may occasionally be a blessing, on the other hand relief can be confidently offered to urgent cases from among the many valuable remedies that may be clearly indicated.

Seasickness—In an opportunity recently afforded Flack to investigate certain aspects of seasickness, it was felt that it would be of interest to see how subjects exposed to the prolonged uneven movements of the sea in rough weather reacted in regards maintenance of ocular poise, pulse and blood pressure. In all, 162 cases were examined. Members of the crew who had not been seasick for many years were used as controls. Ability to maintain ocular poise was tested by means of the Bishop Harmon diaphragm, working, for the sake of convenience, with a fixed pupil distance of 65 mm. On the basis of the study the conclusion is drawn that seasickness is predominantly of vestibular origin due to uneven movement. In certain cases in which the labyrinths are unduly sensitive, vomiting may occur early as the result of reflex stimulation of the vagus motor fibers to the stomach. Such cases are of the type that are also liable to seasickness. In cases of seasickness in which the labyrinth cannot be deemed unduly sensitive, its stimulation early induces or aggravates a degree of ocular muscle imbalance which combined with the continued stimulation of the vestibular apparatus, serves to provoke further symptoms. Generally speaking, subjects in whom eye muscle imbalance is not induced or aggravated do not suffer from seasickness, although a slow pulse and a lowered blood pressure may cause a feeling of "limpness."

Ketosis in Seasickness—According to Marrack, ketosis is usual in seasickness after vomiting has begun, and occasionally appears earlier. Ketosis is not the cause of seasickness nor of any of the symptoms of seasickness. It may be regarded as evidence of some metabolic disturbance the nature of which is not known.

Does Amount of Malaria Depend on Number of Transmitting Mosquitoes?—Important documents on numerical anopheline prevalence and malaria incidence are quoted and discussed by Manalang. The present discord in the opinions of malarialogists is shown to be due to inadequate collection of data and incoordinated observations. A method of study on anophelism in the premalarial transmission malaria transmission and postmalarial transmission epochs that will give adequate and logical information is given. Data collected from ten places consisting of dissections of about 22,000 *Anopheles funestus*

mosquitoes from September, 1927, to December, 1929, inclusive, show monthly and yearly variations in densities in different localities and in different periods of the same locality as measured by systematic catches by trapping with human bait or by exposure. The infective density or number (sporozoite rate) varied in different places, and in the same place in different periods, because of variations in the ever changing human carrier factor. Much malaria with few transmitters and vice versa exist and can be explained by a knowledge of the density and the infective number of the place at the time. Natural unexplained marked decline in density has been observed in two places and explains the sudden disappearance of transmission in certain uncontrolled localities, often attributed to antimalarial measures in controlled areas. The numerical prevalence of the transmitting species alone means little in the epidemiology of malaria, nor can a known density in one locality be utilized for comparative purposes in another. However, the direct relationship of the vector's density to malaria transmission in a locality at a certain period when the corresponding infective number for that locality and period is known has been shown to operate in nature.

Histology and Prognosis of Buccal Carcinoma—Phillips has made a study of 319 cases of buccal carcinoma from the points of view of histology and clinical course, and of 71 cases as regards response to irradiation. The accuracy and usefulness of Broders' histologic classification of epitheliomas have been demonstrated. A well marked correlation between the histology and the clinical course of buccal carcinoma has been obtained. This correlation is found especially in the postoperative length of life, the total duration of the disease and the prospects of cure. These are increased the greater the differentiation of the carcinoma and decreased the greater its anaplasia. No direct relationship was found between the histology of buccal carcinoma and its response to irradiation. A hypothesis is suggested to explain this apparent exception to the general correlation between the histogenesis and the biology of buccal carcinoma. The possible use of this hypothesis in the radiotherapy of buccal cancer is suggested as enabling the most suitable method of irradiation to be applied according to the histology of the growth.

Trigeminal Neuralgia Route of "Hartel" Technic

—Morris prefers the Hartel technic because the route taken by the needle is free from danger and the foramen ovale can be located with accuracy and safety if its relations to both the infratemporal surface of the sphenoid bone and the external pterygoid plate are appreciated. A high, horizontal Hartel route is the most accurate, and with its use it is suggested that it is the sensory root and not the ganglionic tissue itself that is affected by the alcohol. If so the results obtained may be expected to be permanent, and so compare with those obtained by major operation.

Bismuth Oxichloride Ointment in Treatment of Lupus Erythematosus—A preliminary report is submitted by Mac Kennan on the treatment of chronic lupus erythematosus with bismuth oxichloride ointment. Of a series of nineteen cases of chronic lupus erythematosus all of which have benefited from the use of the ointment, ten are reported in detail. Of these five have been cured by the use of the ointment in conjunction with injections of bismuth and the clinical reports indicate that in many cases the disease may be cured by the local application of the ointment without injections of bismuth. Cases have been quoted showing that the ointment appears to have a slight antiseptic or bactericidal effect. The ointment has been employed with advantage in two cases of tinea unguium and two cases diagnosed as chancroid. It is shown that while the ointment may be of value as a local application in the treatment of warts and syphilis it is valuable if administered by injection.

Pathogenic and Clinical Importance of Surface Tension of Urine I Basilewitch—p 1079

Test for Insulin and Dextrose Treatment in Disturbances of Liver—Gornstein and Schwarzmann used Kugelmann's method of determining the dextrose index, that is, they determined the sugar content of the blood immediately before, and again 30, 60, 90 and 150 minutes after an injection of epinephrine given during a period of fasting, and noted the character of the graphic curve as well as the ratio between the highest blood sugar content and the content before the injection. In cases of parenchymatous hepatic disturbances the hyperglycemia usually produced by epinephrine is diminished or entirely lacking; the curve is flattened and the dextrose index is low. The authors used this test in twenty cases of catarrhal jaundice and ten cases of jaundice from arsenamine, in order to measure the success of the insulin and dextrose treatment used. They observed in all cases that the augmentation of the dextrose index was parallel with the amelioration of the general condition of the patient, the disappearance of the jaundice and the appearance of urobilin in the urine. Moreover, the general reaction to the injections of epinephrine became less pronounced as the dextrose index increased.

Importance of Surface Tension of Urine—Basilewitch shows as the result of extensive experimentation that the surface tension of normal urine is slightly lower than that of distilled water and that the surface tension of the urine of an invalid especially in cases of jaundice, is markedly lower than that of water. The author used the capillarmetric method in determining the tension. An analysis of many specimens of urine showed that the pathologic diminution of the surface tension is due in great part to the presence in the urine of biliary acid salts and also at times to the presence of products of decomposition of proteins. It is caused in extremely rare cases by the presence of hemoglobin or of a large quantity of acetone but is never produced by pure colloids. Since the secretion with the urine of large quantities of biliary acid salts and the presence of products of decomposition of proteins is essentially, or even exclusively dependent on the active functioning of the liver, it is clear that the lowering of the surface tension of the urine is a symptom of hepatic disturbances. The author has observed during long clinical experience that diminution of the surface tension appears almost always in cases of jaundice from retention and of parenchymatous jaundice but does not occur in hemolytic jaundice. It is often observed also in diseases of the liver without jaundice, as in atrophic cirrhosis, cancer of the liver and stasis cirrhosis. It appears at times in infectious diseases other than those of the liver (lobar pneumonia, typhoid, scarlatina and measles) in certain intoxications (chloroform, ether, nearsphenamine, lead) in cancerous tumors not of the liver in certain diseases of the blood, for instance, pernicious anemia in severe cases of colitis, and in acute appendicitis. In such cases some more or less important disturbance in the functioning of the liver is evidently involved. The author does not wish to overestimate the semeiologic importance of this symptom but he considers it an important item in the ensemble of clinical and pathogenic information in cases involving hepatic disturbances, with or without jaundice.

Angina Pectoris of Traumatic Extracardiac Origin R Leriche and R Fontaine—p 689

Electrocardiography and Anatomy of Case of Adams Stokes Syndrome E Gerardet—p 704

Angina Pectoris of Traumatic Extracardiac Origin—Leriche and Fontaine report two cases of angina pectoris of extracardiac origin in which the excitation of the sensory cardio

aortic fibers was indirect. In the first case, in which the patient was wounded in the area of the trigonum femorale, the first anginal attack appeared two days after the injury to the limb. In the second case the angina made its appearance ten years after an amputation of the thigh. In the first case a left cervicothoracic sympathectomy was made, i. e., the angina pectoris itself was combated, rather than the original lesion. The results were excellent. In the second case, removal of a painful neuroma at the side of the amputation stump produced a definite amelioration, which, however, lasted only a few weeks. Removal of the left stellate ganglion was equally inefficient. Since the patient refused to undergo another operation the treatment was a failure. The authors believe that in such cases it is advisable to attempt first to suppress the original lesion and if this does not cause permanent relief of the angina, the treatment should then be directed against the anginal syndrome itself.

Azotemia from Acriflavine Hydrochloride. Two Cases.—Richet and Couder report two cases in which injections of acriflavine hydrochloride were followed by marked azotemia. From observation of these two cases and from experiments on animals they feel justified in concluding that certain preparations of acriflavine hydrochloride in the ordinary therapeutic doses produce severe and even fatal azotemic reactions. For this reason one should not exceed a dose of 20 cc. of a 1 per cent solution under ordinary circumstances. If renal disturbances are already present, particular caution should be exercised. If possible every injection should be controlled by a determination of the urea content of the blood about forty-eight hours after the injection, especially if another injection is to follow. Persistent vomiting or nausea is a dangerous symptom. The reason for the hypertoxicity of certain preparations of acriflavine hydrochloride has not been determined.

*Forty-Two Cases of Perforated Gastric and Duodenal Ulcers. P. Wilmoth—p. 712

Arthrodesis of Spinal Column in Scoliosis. M. Fevre and R. Bureau—p. 721

Forty-Two Cases of Perforated Gastric and Duodenal Ulcers.—Wilmoth reports his results in forty-two cases of perforated ulcers of the stomach and duodenum. Of the forty-two patients twenty-one were between 20 and 40 years of age, nineteen were between 40 and 63, and the age of two patients was not recorded. There were thirty-nine men and three women. There were twenty-eight ulcers of the stomach, and eleven of the duodenum. In three cases the localization was not definite. All the ulcers observed were on the anterior wall of the stomach or duodenum. Among the twenty-eight gastric ulcers twenty-one were of the indolent type; there were eight indolent ulcers of the duodenum. It is sometimes difficult, if not impossible, to detect the development of an ulcer before the perforation takes place, and the absence of preliminary symptoms of pain and digestive disturbances makes a correct diagnosis difficult in the face of a violent onset of pain similar to that observed in appendicitis. The author believes, however, that errors in diagnosis may be avoided by taking account of the following three symptoms: (1) the absence of fever above 38°C (100.4°F); (2) a slight acceleration of the pulse which during the first twelve hours rarely exceeds 90; (3) muscular

contraction, always more pronounced in the supramesocolic region. Moreover, prehepatic tympanism usually present in acute appendicitis, was absent in all of the forty-two cases of perforated ulcer observed by the author. Absence of vomiting is also a significant symptom. The importance of an early diagnosis, in order that an operation may be performed within the first ten or twelve hours, is generally recognized. Among the forty-two cases reported eleven operations before the sixth hour gave eleven cures, seventeen operations between the sixth and twelfth hours gave nine cures and eight deaths, and eight operations between the twelfth and twenty-fourth hours gave five cures and three deaths. In six cases the exact time of the operation was not recorded. In thirteen cases the operation used was merely burial of the perforation by means of one or two purse-string sutures. In twenty-four cases burial completed by a posterior gastroenterostomy was used, when the suture caused stricture of the pylorus or duodenum. There were two deaths among the patients treated by simple suture of the perforation and five among those in whom the burial was complemented by a gastroenterostomy. The author regards burial as the operation of choice, a gastroenterostomy being added when it seems advisable in order to favor cicatrization of the perforation.

Functional Exploration of Liver and Reticulo-Endothelial System. M. Ronzini—p. 333

Experimental Renal Mycosis Due to *Cryptococcus Interdigitalis*. P. Barco—p. 401

Functional Exploration of Liver and Reticulo-Endothelial System.—Ronzini, on the basis of experimental and chemical researches in which he used bengal rose as a dye, the mechanism of the disappearance of which from the circulation is associated with the chromopexic power of the reticulo-endothelial system and with which he combined the test of the plasmatic biliary index, concludes: 1. Of the anesthetics, chloroform modifies intensely the behavior of cholemia and of bengal rose during the first five to seven days. The influence exerted by ether is uncertain and inconstant. Local and segmental anesthetics produce no modification. 2. Of the surgical traumas, only those affecting the liver and the biliary tracts cause functional defects in the hepatic cells while the influence of operative traumas usually remains negative. 3. The subjects showing previously modified results with the bengal rose test and the test of the plasmatic biliary index become more easily a prey to postoperative complications and the cases with a complicated postoperative course are always early associated with an increase of the percentage of bengal rose and of bilirubin retained in the blood.

Experimental Renal Mycosis Due to *Cryptococcus Interdigitalis*.—Barco injected directly into the renal parenchyma of experimental animals (dogs) a culture of *Cryptococcus interdigitalis* diluted with Ringer's solution. From histologic observations made after various periods of time (15, 45, 90, 120 and 150 days) after the inoculation, he concluded that *Cryptococcus interdigitalis* in an attenuated culture and with suitable technique develops in the renal parenchyma giving rise to the formation of a so-called mycotic granuloma, which assumes the characteristics of a hyperplastic process of a chronic type and with the tendency at first to extend further, followed, in turn by a progressive involution brought about by the connective tissue of the elements that surround the mycoma itself.

*Some Rare Forms of Renal Tuberculosis. G. Tarozzi—p. 3
Mixed Hypernephroid Tumors of Kidney. C. Tedeschi—p. 100

Rare Forms of Renal Tuberculosis.—Tarozzi brings out that renal tuberculosis, in all the forms in which it is manifested must be regarded, almost without exception as of hematogenic origin, and in the beginning at least as bilateral and in renal tuberculosis apparently unilateral, isolated miliar

tubercles are usually found in the other kidney, often in the course of evolution, or there may be only cicatricial remnants of milinary tubercles. The localization of the initial hematogenic tubercle in the vicinity of a papilla, and its extension over the papillary surface is the condition that most facilitates the later evolution and diffusion of a tuberculous process in the kidney while the primary hematogenic milinary foci distributed throughout the mass of the kidney usually tend after a varying period of slow evolution, toward spontaneous retrogression and also cicatrization.

Anatomopathologic Clinical and Therapeutic Considerations on Malignant Tumors of Stomach Submitted to Radical Operation F. Rossi —p 1207

Sarcomatous Epulis Due to Irritation of Foreign Body Embedded in Tooth Socket A. Citterini —p 1292

Postoperative Bronchopneumonia G. Oselladore and A. Luisada —p 1307

Consideration of Malignant Tumors of Stomach Radically Operated On—Rossi reports that from 1919 to 1927 the neoplasms of the stomach diagnosed in the Clinica chirurgica di Milano amounted to 228. Of the patients 28 or 12 per cent were not operated on. 50 or 13 per cent were subjected to a simple exploratory laparotomy. 87 or 38 per cent to a gastro-enterostomy. 83 or 45 per cent of those operated on, were subjected to resection of the stomach. The author discusses these in detail. Three were sarcomas the others, carcinomas. The average postoperative mortality was 33 per cent. Of those who were cured surgically twelve had left the neighborhood. Of the others, two were still living after nine years, two after seven years, two after six years, and two after five years. Important anatomopathologic, clinical and therapeutic considerations are given.

*Maternal Factors in Development of Rickets G. Macciotta —p 923

Maternal Factors in Development of Rickets—Macciotta discusses the intra uterine origin of rickets. He believes that several toxic or infectious factors such as syphilis, malaria, tuberculosis or auto-intoxication or conditions of either alimentary or endocrine insufficiency act on the fetus through the organism of the mother. In 40 per cent of 735 rachitic children aged from 2 months to 2 years, observed by the author, such maternal factors appeared as the etiologic factors of the disease. The author made an experimental study on animals either pregnant or recently after delivery in connection with his clinical observations. He found that when pregnant animals are deprived of phosphorus, the offspring show precise histologic, roentgen and morphologic manifestations of experimental rickets which manifestations are not so marked when they are deprived of calcium only, the quantity of phosphorus being normal. This fact, the author believes, proves the role that hypophosphatemia rather than hypocalcemia plays in the development of rickets. The offspring of animals which during pregnancy have been kept in dark places receiving normal diets but no light show manifestations of rickets probably caused by the condition of hypophosphatemia, which is observed in animals kept in dark places. The offspring of animals treated during the entire period of pregnancy with thymic, suprarenal or hypophyseal extracts as well as those of animals subjected to total thyroidectomy during pregnancy, were normal. Litters of animals that received extract of total thyroid during the entire period of pregnancy develop grave forms of rickets associated with nutritional disturbances usually incompatible with the life of the animals. The deprivation of antirachitic factors in the alimentation of mothers either during pregnancy or during nursing causes the development of rickets in the offspring. The author discusses the mechanisms involved in the development of rickets in which cellular metabolic and constitutional disturbances cause certain conditions in the fetus through the maternal organism which later during the extra-uterine life prevent the normal development of the processes of ossification. By applying the observations of his experiments to human beings the author concludes

that prophylaxis of rickets in infants should start during the fetal period and be continued during the nursing period in both instances through the organism of the mother.

*Spasmophilic Forms of Enuresis in Children G. Macciotta —p 1145
Changes of Potassium and Calcium Metabolism in Peptone Shock with Circulatory Insufficiency E. Schiff, H. Eliasberg and A. Mazzco —p 1118

*Behavior of Blood Fibrin in Several Types of Anemia E. M. Mondini —p 1162

Spasmophilic Forms of Enuresis in Children—Macciotta considers two forms of nocturnal enuresis in children: essential and secondary nocturnal enuresis. The first mentioned form is only a symptom of certain pathologic conditions of the child. The author reviews the several theories on the pathogenesis of essential nocturnal enuresis. He believes that there is a relation between the disease and an increased excitability of the nervous system. He reports the results of his observations in twenty-four enuretic children aged from 2 to 6 years. Cases of secondary enuresis or conditions of a pseudo enuretic type such as the habit of children to urinate in bed because of poor bringing up or psychic inferiority as well as those forms of enuresis in which the disease could be caused by influence of pathologic conditions of the lumbar portion of the vertebral column of the spinal cord or of the genitalia or of the urinary tract were excluded from this group. Most of the children observed had some familial nervous taint especially alcoholism, and less frequently hysteria or epilepsy. In seventeen of his cases the author found a more or less marked increase of the galvanic excitability, hypocalcemia and slight diminution of the ionic concentration associated in some of the cases with manifestations of mechanical hyperexcitability. He considers these cases of essential nocturnal enuresis to be manifestations of spasmophilia in which the individual local nervous constitution causes the nervous stimulus which the detrusor urinae receives to be physiologically sufficient (especially while sleeping). The author obtained rapid and almost constant cure of essential nocturnal enuresis in his group of children with treatment by ultraviolet rays. His results were still better when the ultraviolet irradiations were given in association with the administration of vitamin B, the treatment having been complemented in some cases with the administration of parathyroid hormone.

Behavior of Blood Fibrin in Several Types of Anemia—In order to determine the behavior of blood plasma fibrin in anemia of different causes and different types Mondini made estimations of the fibrin content of the blood plasma first in ten normal children aged from 1 to 8 years on which to base his studies and then in twenty-five children aged from 1 to 12 years with primary or secondary anemia of a regenerative or nonregenerative type. In both groups of children the fibrin content of the blood plasma was about the same as that in older children. In normal children the fibrin content of the blood plasma gave an average of 3.68 Gm. per thousand cubic centimeters. In the group of anemic children the variations of the fibrin content of the blood depend more on the etiology of the anemia than on the type of the disease. The forms of pseudo-leukemic and hypoplastic anemia and kala-azar are associated with hypofibrinemia. The intensity of hypofibrinemia is in relation with the maximum degree of anemia. The types of anemia secondary to metapneumonic emphysema and anemia of the second period of tuberculosis are associated with hyperfibrinemia. The content of fibrin in the blood plasma of patients with anemia caused by purpura hemorrhagica or any other type of post-hemorrhagic anemia is normal. The changes that the fibrin of the blood plasma undergoes in several types of anemia make the author suspect a probable relationship between the bone marrow and the formation of fibrinogen.

Etiology of Lipoid Nephrosis R. Rinaldi —p 1701
*Treatment of Perforated Duodenal Ulcers S. Jugh, A. Allegra —p 1707
Case of Kala-azar. Cure Effected by Splenectomy J. Turiano —p 1710

Treatment of Perforated Duodenal Ulcers—Puglisi Allegra recites the results secured in the treatment of perforated duodenal and juxta-pyloric ulcers by a surgical procedure based

on a constant anatomicopathologic observation, namely, the restriction of the peritoneic process, for a considerable period, to the right hypochondrium and the diffusion of the exudate toward the right renal pocket. He performed a posterior transmesocolic gastrotomy, watching carefully with every maneuver for the perforation in order not to spread the infective process. By means of a wide curvilinear midaxillary incision under the costal arch an opening was obtained that permitted, with great facility, the treatment of the ulcer (cauterization and suture) and suitable drainage.

Autohemolytic Power of Various Organic Fluids in Man A Montanari —p 937

India Ink Test as Applied to Cerebrospinal Fluid A Greco —p 963

Autohemolytic Power of Various Organic Fluids in Man—Montanari tested the autohemolytic power of 139 human organic fluids (97 blood serums, 27 cerebrospinal fluids and 15 exudates and transudates) and studied the special nature and the diagnostic value of such power. He found in two blood serums a small amount of a true, nonspecific autohemolysis, associated in each case with icterus. In five other cases there was a weak chemicophysical hemolytic power that had no particular relations with the age of the subject, the disease or a positive Wassermann reaction. In the spinal fluid of a syphilitic person he found a true autohemolysis and in twenty-four other cases a weak chemicophysical hemolytic power that must be regarded as physiologic and persistent in pathologic conditions. As to transudates and exudates he found an absence of hemolytic power in the former and presence of hemolytic power of a weak chemicophysical type in about one third of the latter and proportional to the albumin index.

India Ink Test as Applied to Cerebrospinal Fluid—Greco has found the india ink test as applied to the cerebrospinal fluid by Benedek and Thurzo of value in the examination of the cerebrospinal fluid. He confirms that a negative reaction of the cerebrospinal fluid excludes with certainty pathologic changes as well as the ordinary means of research. As regards the positive reaction, however, the characteristic value of the colloiddoprotective index assigned by Benedek and Thurzo to the various diseases of the nervous system must be accepted with reservations in view of the difference in the observations in a given disease and the similarity of the observations in different diseases. In the mechanism of the reaction the globulins present in the cerebrospinal fluid are very important and the value of the colloiddoprotective index in pathologic fluids is apparently in relation to the quantity of globulins. The test gives therefore a useful indication in regard to the amount of globulins in the cerebrospinal fluid.

*Value of Arneth's Formula and Erythrocyte Sedimentation Test in Prognosis of Pulmonary Tuberculosis A Curti and J Stephani —p 977

*Phrenic Avulsion in Pulmonary Tuberculosis G Forni —p 985

Disinfection of Wools Infected with Tuberculous Products—Giovanardi states that chloramine is a good disinfectant of contaminated wools also efficacious when tuberculous products such as dried sputum are involved. For the ordinary disinfection of woolen garments at least a 3 per cent solution is required the garments being left four hours or more in the solution. If an especially effective concentration is desired a 5 per cent solution applied for from two to four hours is recommended.

Arneth's Formula and Sedimentation Test in Prognosis of Tuberculosis—Curti and Stephani describe the technique of the erythrocyte sedimentation test and the technique of the Arneth research on neutrophils and point out the causes that may produce variations in the results of the sedimentation test. From

the results of the two tests carried out systematically on seventy patients, they assign a greater value to the Arneth formula, which appears to be more reliable than the sedimentation test, not only as to the various phases of the disease but also as to the remote outcome.

Phrenic Avulsion in Pulmonary Tuberculosis—Forni reports the results of phrenic avulsion performed on twelve women ranging between 19 and 35 years of age and on eight men between 20 and 30 years of age. After an interval of two years in some cases and of at least eight months in other cases, the results as deduced from the manifestations of the general condition and from objective roentgen and laboratory data can be summarized as follows. Rapid and enduring improvement was shown in four of the six patients affected with sclerotic infiltrative processes. In the other fourteen patients there was a good result in three cases, perceptible improvement in three others and slight if any improvement in five cases. Three patients died, one from hemoptysis and two from cachexia. A clinical recovery in the sense of an incomplete but economic recovery was effected in seven patients, in three there was a perceptible improvement although the tuberculous process remained in an evolutionary stage in the remaining seven the improvement was slight and perhaps will be nil if the process should progress and spread. It is certain that phrenic avulsion constitutes, under some conditions one of the best means of facilitating, with fibrous neoformation, cicatrization of the lesions.

*Globular Resistance and Cholesteremia in Icterus C Velasco Suarez and M Etcheverry —p 823

Unusual Results of Therapeutic Pneumothorax in Pulmonary Tuberculosis J Dutrey —p 826

Influence of Pregnancy on Pulmonary Tuberculosis—Ramondt made a comparative study of 446 nonpregnant tuberculous women and the same number of pregnant tuberculous women. The two groups had similar forms of tuberculosis in its different stages (first, second or third stages). From his observations the author concludes that the evolution of tuberculosis in pregnant women depends more on the clinical form of the tuberculous lesion in the lung than on a direct injurious influence of pregnancy on tuberculosis. Tuberculous women should not become pregnant but, once the patient is pregnant, the proper conservative treatment should be given and the interruption of pregnancy as a systematic method should be avoided. In pregnant tuberculous women with progressive unilateral tuberculosis, the induction of therapeutic pneumothorax is advisable. Tuberculous patients who at the beginning of pregnancy present grave disturbances of digestion which are not improved by treatment with absolute rest probably cannot bear well the pregnancy. In these patients the interruption of pregnancy is advisable. Tuberculous patients who after a stationary period of tuberculosis show a reactivation of the disease during the first months of pregnancy may benefit from the interruption of pregnancy. In some patients the disease stops during pregnancy and the lesion enters a stationary period. This improvement in the patient's condition is caused by the elevation of the diaphragm which gives the pathologic lung relative rest. In these patients the thoracic compression should be performed immediately after delivery to avoid a possible aggravation of tuberculosis caused by the sudden decompression due to the dropping of the diaphragm to its normal position.

Globular Resistance and Cholesteremia in Icterus—Velasco Suarez and Etcheverry made determinations of the cholesterol content in the blood of patients with several types of icteric syndromes in relation with the globular resistance and the hematologic formula of the patients. They reach the following conclusions. There seems to exist a relationship between the cholesterol content of the blood and the resistance of erythrocytes to hemolysis. The larger the cholesterol content of the blood the greater the increase of the globular resistance. On the contrary, a normal or diminished cholesterol content of the

blood is associated with either normal or diminished globular resistance. In the majority of cases of icteric syndromes both the number of erythrocytes and the amount of hemoglobin are diminished, regardless of whether the globular resistance is increased or diminished. In forms of obstructive jaundice the anemia is of the secondary form and is of slight intensity. In splenomegalic hemolytic jaundice, on the contrary, the anemia is of a grave nature. The authors state that the physiopathogenesis of icteric syndromes is not sharply defined. In the etiology of obstructive jaundice syndromes, besides the mechanical factor which is the direct cause of jaundice, hyperhemolysis has an important role as the determining factor of hyperbilirubinemia.

- *Serous Meningitis from Cranial Fractures. M. Gomez Duran—p. 569.
Gout Pathogenesis. Hydrotherapy. C. Garcia de Cosa—p. 574.

Serous Meningitis from Cranial Fractures.—Gomez Duran reviews the symptoms that lead to an early diagnosis of serous meningitis when a trauma with possible cranial fractures has been received. As treatment the author advises intravenous injections of a 50 per cent solution of dextrose in doses of 200 or 300 cc a day. The mechanism of action of the dextrose solution, as well as of hypertonic solutions of sodium chloride or Ringer's solution, is that it causes modifications of the osmotic pressure. Hypertonic solutions when administered early give gratifying results by reducing the increased intracranial pressure. The author reports the case of a syphilitic patient, aged 20 who after a trauma of the head developed serous meningitis. He believes that in this case syphilis caused a special condition of the cerebral meninges which condition favored the development of serous meningitis when the trauma was received.

Mode of Action of Paraffin Treatment. H. Lampert—p. 2084.

Charcoal Therapy in Febrile Abortion.—Benthin reports his experiences with charcoal therapy in febrile abortion. He was induced to employ charcoal in such cases by the favorable results that had been obtained with it in veterinary medicine. What makes charcoal especially suited for the treatment of febrile abortion is its great adsorptiveness, the capacity for fixation of the microorganisms, the power to detoxicate to check the resorption of toxins and to hasten the discharge of the pathogenic organisms. In regard to the technique of charcoal therapy the author states that he introduces sterile charcoal pencils into the uterus where they dissolve. Occasionally undissolved pieces are later found in the cervix or in the vagina. However, in the uterus they become completely dissolved. The author employed this method during the last four years in 300 cases. Only one of the patients died. In 10 per cent of the cases minor complications developed. Serious complications developed in five cases. The method has been investigated in several clinics and objections have not been made. It was also found helpful in cases of puerperal endometritis. In summing up the advantages of charcoal therapy the author stresses the simple technique, which permits its application in general practice. The duration of the disease is considerably reduced and the dangers of active intervention are lessened by preliminary introduction of carbon pencils. Other advantages are the deodorizing effect of charcoal and the furthering of the discharge.

Paradoxical Embolism Especially After Confinement

—Kressin reports the case of a primipara aged 30. On the eleventh day after confinement severe pains were felt in the calf of the right leg and several hours later the patient complained of pains in the right side of the chest. A pulmonary infarct was demonstrated. On the following day the patient got up against the physician's orders. She collapsed and soon

afterward felt severe pains in the left leg. On the following day the case was diagnosed as arterial embolism in the region of the left leg. About sixty hours after the development of the embolism the patient was brought to the hospital. Here the case was diagnosed as paradoxical embolism with obstruction of the left femoral artery. An operation was performed, but the woman died seven hours later. The results of the necropsy are reported and it is assumed that the embolus developed from a puerperal thrombosis of the right femoral vein and that through a persistent foramen ovale it reached the artery. The author emphasizes the significance of an early diagnosis and immediate surgical treatment. If the operation is performed during the first five hours 70 per cent of the patients recover; if ten hours has elapsed only 50 per cent recover and the literature contains a report of only one case in which the operation was successful forty-eight hours after the development of the embolism.

Spleen Extract in Treatment of Pulmonary Tuberculosis.—Because other authors had obtained favorable results with spleen diet in severe febrile tuberculosis Leitner employed spleen extract in the treatment of forty-one patients with pulmonary tuberculosis. Thirty-five of these patients were in the third stage of the disease and six were in the second stage. In all cases bacilli could be detected, and thirty-six had caverns. In fifteen patients the larynx was involved. The patients were given daily an amount of spleen extract equivalent to 120 Gm of fresh spleen. The treatment was continued for from six weeks to five months. Of the forty-one patients, twenty-four were not influenced by the spleen therapy. Of the other seventeen patients, one with exudative tuberculosis showed a marked improvement. The patient's weight increased, the temperature decreased and the pulmonary process became latent. The other sixteen patients showed improvement particularly in the general condition, such as increase in weight, decrease in the temperature and in some cases also a decrease in coughing and in the quantity of sputum. However the pulmonary process only became temporarily stationary but did not show improvement. The laryngeal processes were not influenced. The author did not obtain such favorable results with spleen therapy as did some other investigators. But because the treatment never has harmful effects, and in some cases gives favorable results a trial is justified especially in cases in which other therapeutic methods cannot be used.

Function of Interstitial Cells of Testis Studied on Guinea-Pigs with Experimental Tuberculosis.—Ziegler points out that of the cellular elements of the testis Sertoli cells in the tubules and Leydig cells of the interstitial tissues deserve especial attention because their functional significance and their relation to the semimurous tubules is still not entirely understood and some of the explanations are contradictory. He studied these problems by carefully observing the changes in the testes of tuberculous guinea pigs. On the basis of his observations he comes to the conclusion that the Sertoli cells of the tubule and Leydig cells of the interstitial tissues are cell forms which genetically and functionally are of equal value and which are the parent cell of spermatogenesis. A specific system of interstitial cells which genetically and functionally differs from the semimurous system does not exist. The interstitial cell formations in the course of atrophic processes

or during reparatory growth processes are fluctuating manifestations. They are either tubules in the process of reduction or newly forming seminiferous tissues. The author is in agreement with those investigators who consider tubules and interstitial cells as one tissue system that has the hormonal secretion in common. This theory would also explain the fluctuations in the extension of the interstitial cell system in the various pathologic conditions, in cryptorchidism, in eunuchoidism, in inanition and in phthisis. The cells adapt themselves to the unfavorable nutritional conditions by changing into that form which is best suited to the reduced metabolism. They have a greater resistance against injurious influences and retain their potential energy.

Pathogenesis of Erythremia and of Leukemia—According to Weber and Bode, the main argument for the theory that erythremia is due to an excessive formation of erythroblasts by the bone marrow is the occurrence of cases in which erythremia and leukemia are combined, that is in the blood picture both the white and the red corpuscles show an abnormal increase. Such cases, which are designated as erythroleukemia, may differ widely from one another; however, they all represent links of a chain, on the one end of which stands erythremia and on the other end leukemia as proof of an excessive hematopoietic activity. Many investigators oppose a comparison between erythremia and myeloid leukemia on the ground that in erythremia there exists an excessive number of mature blood cells, whereas in myeloid leukemia there appears in the blood stream a large number of immature forms. Against this argument it can be said that there are rare forms of leukemia in which the increased number of leukocytes consists largely of mature cells. The authors consider the neoplastic theory as the most reasonable explanation for myeloid leukemia, for erythremia and for the entire erythroleukemic group. This neoplastic process becomes manifest (1) as erythremia in an exclusive erythroblastic hyperfunction, (2) as erythroleukemia when the erythroblastic and myeloblastic functions are both affected, (3) as erythremia followed by myeloid leukemia when first the erythroblastic and then the myeloblastic actions are involved, (4) as myeloid leukemia followed by erythremia when the reverse is the case, and (5) as myeloid leukemia when only a myeloblastic hyperactivity exists.

Uremia in Scarlet Fever Nephritis—Altmann observed that scarlet fever develops at present mostly in the less severe forms and the complications are likewise slight. Only nephritis has become more frequent and also more severe. In spite of the fact that a strict diet was instituted immediately after nephritis had become manifest, uremia developed in one out of five patients and some of these cases had a fatal outcome. In order to determine in what cases of scarlet fever nephritis the development of uremia may be expected, the author determined the rest nitrogen and carefully observed diuresis, hematuria and albuminuria. However, it was found that uremia develops independently of the renal function and that there are no sure signs of a threatening uremia. It is not possible to differentiate between various forms of uremia on the basis of an increase in the rest nitrogen during acute nephritis. Whether spasmic uremia of acute nephritis and silent uremia during chronic nephritis are two different diseases could not be determined.

- Criticism of Methods of Passive Transmission of Hypersusceptibility E. Urbach—p 2304

Treatment of Rickets by Small Doses of Quartz Lamp Radiation.—Vollmer points out that whether large or small doses of ultraviolet rays are applied, the results are about the

same. This indicates that in many cases too large quantities are applied, which not only overburden the child but also are a waste of time and of electric power. Forty-three nursing children, whose care was supervised in a health center, were given a quartz lamp treatment once a week. The rays were applied for from four to five minutes each on the chest and back. The distance was 80 cm. In infants in whom the rickets was especially severe, the irradiation was at first given twice weekly. With this method most cases of rickets were cured after 100 minutes of treatment with the quartz lamp, and, once cured, the children had no relapse during the winter. The author thinks that a weekly irradiation of from four to five minutes on the chest and back is the minimal effective dose. Between the minimal dose for prophylaxis and for treatment there is no great difference. The results obtained with minimal doses are more favorable than those obtained with other treatments of rickets.

Distribution of Blood Groups in Spain—Andreu Urra determined the blood groups of 904 persons. Among this number were persons from all parts of Spain, but those from the central provinces predominated. The author puts especial emphasis on this fact because in the central parts of the country all race elements, Romanic, Gothic and Arabic, are mixed, whereas in the northern parts the mixture is not so complete. The invading peoples did not remain long in the northern provinces but migrated to the central and southern parts of the country. Of the 904 persons examined, 20.3 per cent showed group I (O), 50 per cent belonged to group II (A), 15.7 per cent to group III (B) and 13.9 per cent to group IV (AB). The race biologic index of the Spanish population, according to Hirschfeld's formula, is 22. In comparing the percental distribution of the blood groups among the Spanish population with those among other Latin peoples, the author found that the distribution of groups II and III is much like those in other Latin countries. However, the percental distribution of groups I and IV is much different in Spain than in other Latin countries. Whereas in other countries only from 3 to 7 per cent belong to group IV, in Spain 13.9 per cent belong to this group and whereas in other Latin races from 36 to 50 per cent of the people belong to group I, in Spain only 20.3 per cent have this type of blood.

Cancers in Region of Lower Liver—The cancers in the region of the lower portion of the liver represent a special clinical group, and for this reason Pelnar discusses them together. To this group belong cancers of the gallbladder, of the biliary tract, of the duodenal papilla and of the pancreas. Each of these cancers has typical symptoms, but all of them have certain manifestations in common. After discussing the frequency of these cancers, the author describes the symptomatology of each of them. A comparison of the clinical pictures shows that the cancers of the region of the lower liver become manifest as lingering, cachectic diseases without fever and without chemical or roentgen signs of cancer of the stomach and without marked anemia. The liver becomes enlarged without perceptible nodules and frequently the gallbladder is palpable. In the beginning of the disease or during its course mechanical icterus or atypical pains in the epigastrium develop. Sometimes these two symptoms concur. As a rule the patients do not appear very pale, generally they have a neutrophilic leukocytosis. Only in rare cases is resistance noted over other organs besides the gallbladder. Of the special diagnostic methods, roentgenoscopy will reveal that a progressive disease process exists in the region between the pre-

pylorus and the duodenum but that cancer of the stomach is absent. Examination of the duodenal contents gives indications that the flow of bile and of the pancreatic secretions has stopped or of hemorrhages from the duodenal mucous membrane. The determination of the glycemic curve indicates disturbances in the internal secretion of the pancreas. These may be caused either directly by a tumor or indirectly by cachexia. Benign processes which are of significance in the differential diagnosis are cholelithiasis and cholecystitis. In cholelithiasis cachexia is almost never present, and cholecystitis usually has an acute initial stage. Most significant for an early recognition is that cancer is thought of. The exact localization of the tumor is not so essential. The internist and the surgeon should cooperate. An early exploratory laparotomy is advisable. Only if the cancer is removed in the beginning stage can good results be obtained.

Regeneration of Bones Destroyed by Tuberculous Processes.—Jerusalem reports the clinical history of a patient with severe exudative posttraumatic tuberculosis of the wrist joint as well as of the proximal terminations of the metacarpal bones. For ten months the process was destructive and after that for about a year regeneration could be observed. Several roentgenograms show the process during the successive stages of destruction and regeneration. The process was treated by repeated punctures and irrigations. For three months the patient was placed on a spleen diet and in the course of one year several series of roentgen treatments were given. The rays were applied through a filter of 0.3 mm of brass and 1 mm of aluminum. One fifth of a unit skin dose was applied during each session. To what extent the regeneration was induced by the treatment cannot be definitely ascertained but it is probable that the immobilization of the joint by a fixation bandage was helpful. The repeated punctures and irrigations may likewise have been a therapeutic aid and since roentgen therapy has proved helpful in many forms of surgical tuberculosis, it cannot be doubted that the regeneration was largely due to the roentgen treatments. As an essential factor the author considers the strict aseptic treatment of the fistulas. The asepsis prevented a secondary infection with cocci and thus one of the most serious complications of tuberculosis of bones and joints, namely, a mixed infection was avoided.

Hematuria in Cholecystopathy.—Edelmann asserts that while formerly a relation between disturbances in the biliary tract and renal disorders was not thought of, in recent years the literature has contained several reports of such relations. In cases that show all the symptoms of nephritis the diagnosis is usually not difficult. However in cholecystopathy in which microscopic hematuria is the only sign of renal disorder the diagnosis is more difficult. The author made observations on a large material. In about 3 per cent of the cases of cholecystopathy microscopic hematuria could be detected. Characteristic symptoms were absent. The complaints gave just as much indication of a gastro intestinal disorder as of disease of the gallbladder. The author found it best, whenever the symptoms were not characteristic to refrain from instrumental urologic examination and first to employ other diagnostic aids. Of great help was roentgenography of the entire urinary tract. When no signs of a disorder of the urinary apparatus were found, roentgenography occasionally gave indications of an extrarenal disturbance, especially of the gallbladder. Whenever the roentgen examination gave no indications whatever either the gallbladder or the urinary tract was examined. In some cases intravenous cholecystography resulted in a correct diagnosis. In many cases a control examination of the urinary tract was made. However, in case of a disorder of the gallbladder there never existed a disturbance in the urinary tract. In spite of the microscopic hematuria the urinary tract was found healthy. When the cholecystopathy was cured and following operative removal of the gallbladder all cellular elements disappeared from the urine. This proved the correctness of the diagnosis pseudorenal disease. On the basis of these observations the author stresses that whenever a cholecystopathy is probable, cholecystography should precede the more serious instrumental urologic examination.

Primary Sarcoma of Heart.—Duncke reports the clinical history of a man aged 26. The first symptoms indicated a

gastric disorder and later pulmonary symptoms appeared. Because roentgenoscopy of the lungs revealed pulmonary tumors, a primary cancer of the stomach with pulmonary metastases was thought of. Exploratory laparotomy revealed that the stomach and duodenum were free from pathologic changes. The patient died. The necropsy revealed a spindle cell sarcoma of the heart with metastases in the lungs. It seems surprising that in spite of the great extension of the sarcoma in the heart cardiac symptoms were not observed. However, in several other reports on tumors of the heart in which the right auricle was nearly completely obliterated, signs of congestion were likewise absent. The author thinks that the gastric symptoms, which were predominant in the case reported were caused by an increased irritability of the vagus. On the left side this nerve was completely surrounded by tumor masses. The pulmonary symptoms which were thought to be due to a tuberculous infiltrate were the result of pulmonary metastases of the primary sarcoma of the heart.

Cancer. Comparison of Results of Single and of Fractional Irradiation.—Juul describes experiments that he performed on white mice with inoculation cancer to compare the effects of a single roentgen or radium irradiation with the effects of fractional irradiation. As an index of the action of the irradiation he used three criteria, namely, the rate of growth of the tumor, the number of animals in which the tumors were made to disappear and the average length of life of the animals in which the tumor persisted. He found that with both roentgen and radium rays the results obtained when the irradiation was given in one large dose were better than they were when it was given in fractional doses.

Changes in Lungs Following Roentgen Irradiation.—Ludin and Werthemann studied the changes produced in the lungs of twelve rabbits by roentgen irradiation of the thorax. They summarize their observations thus: In all of the rabbits there was noted a bronchopneumonia with severe suppurative bronchitis. The alveolar epithelium underwent degeneration characterized by swelling and vacuolar degeneration of the protoplasm and disappearance of the nuclei. In the region of the bronchopneumonia areas there was marked pulmonary edema with desquamative catarrh. In the bronchial epithelium marked proliferation was noted in some places the epithelium had become stratified and its growth had resulted in the production of carcinoma like pictures with numerous atypical mitoses, cell polymorphism and pyknosis and disintegration of the nuclei.

Changes in Myocardium Following Roentgen Irradiation.—Werthemann divides the changes that he observed in the myocardium of rabbits following roentgen irradiation of the heart thus: (1) parenchymatous injuries which include simple cloudy swelling with loss of the transverse striation, degeneration of the cells with disappearance of the fibril striation

atrophy of the muscle fibers proceeding in some to their complete disappearance and simple disappearance of the nuclei with marked diminution in the number of nuclei in the degenerated parts and (2) changes in the interstitial connective tissue, which include perivascular and extensive diffuse inflammatory infiltration and the formation of milium and sclerotic indurations.

Tabetic Crises Roentgen Irradiation—Kremser describes the technique he used in the roentgen irradiation of the spinal cord in forty-four persons with tabetic crises. In eleven of the patients the treatment was without effect. In four of them, slight improvement was noted. In twenty of the patients there was marked but only temporary improvement. Nine of the patients were completely free from symptoms for a long time. The observation of Ahringsmann and Illig that in the majority of cases the improvement is preceded by an increase in the intensity of the prisms was not confirmed.

Primary Closure of Abdominal Wall in Appendectomy

—On the basis of eight years' experience Muller discusses whether primary closure of the abdominal cavity or drainage gives the best results in appendectomy. Tabular reports indicate that if drainage is used there is a certain percentage of fatalities, whereas without drainage the mortality is zero. The author thinks that drainage is done too frequently and that primary closure of the peritoneum and of the subcutis should be done in all cases of acute appendicitis without severe complications. In gangrene or perforation of the appendix the number of cases in which primary closure without drainage was done is still limited. However, the experiences in a small number of such cases speak for primary closure. The author asserts that drainage retards the healing process. He thinks that neither serous nor cloudy exudates necessitate a drainage tube, a strip of gauze or drainage thread. The gauze and the thread hinder the discharge of the secretion and cause congestion. And it is also probable that the presence of the foreign body leads to excessive secretion.

Vaccination Encephalitis Effect of Poor General Condition on Course of Vaccination—Eckstein and Sarvan observed the course of intracutaneous vaccination in three control monkeys, in four in which the spleen had been removed in three with chronic hunger and in three with chronic alcohol poisoning. In the control animals the local reaction appeared on the third or fourth day following the vaccination and healed in from eight to twelve days. The blood of the animal treated with the smallest amount of lymph showed on the twenty-first day the greatest virucidal power. The blood of the two other animals also showed a positive virucidal power. The local reaction in the animals with chronic alcohol poisoning did not differ from the reaction in the control animals. The

fasting animals showed a retarded local reaction and the vaccine pustule tended to undergo ulceration and healed slowly. In two of the animals that were successfully vaccinated it was found that twenty-one days after the vaccination the virucidal power of the blood was increased. In a third animal with a greatly lowered general condition the vaccination was unsuccessful and the virucidal power of the blood was not increased. In two of the splenectomized animals the course of the vaccination was the same as that in the control animals. In one animal the vaccine pustule did not appear until the sixteenth day after the vaccination and it persisted twelve days. On the forty-fifth day a recurrence with pustule formation appeared and underwent ulcerative degeneration. In the contents of the pustule it was possible to demonstrate the vaccine virus. The virucidal power of the blood was not increased. In another animal two vaccinations were not followed by the development of a local reaction although on the nineteenth day following the first vaccination the vaccine virus was present in the blood. In this animal also the virucidal power of the blood was not increased. None of the animals presented manifestations of a nervous disturbance. Even in the splenectomized animal that reacted with a recurrence in the form of a generalized vaccination and that died from the results of a puncture of the heart neither microscopic nor macroscopic examination of the brain revealed any manifestations of encephalitis. Emphasis is laid on the fact that although the course of the vaccination in the fasting and splenectomized animals was greatly disturbed it was not followed by the development of a so-called vaccination encephalitis.

Vaccination Encephalitis Permeability of Meninges in Normal Course of Vaccination—By means of Walter's bromine method, Eckstein demonstrated that in none of nine normal infants aged from 5 months to 1 year and 10 months was vaccination followed by an increased permeability of the meninges. Neither the number of the vaccination pustules, the intensity of the vaccination reaction nor the height of the body temperature was in relation to the permeability of the meninges. Since the bromine quotient in all the infants corresponded to the normal it is obvious that in the late nursing age vaccination is not followed by an increase in the permeability of the meninges.

Unipolarity of Air Ions—Belak et al. describe a method by means of which it is possible in a closed chamber to produce a unipolarity of the air ions. In experiments on human beings in which the blood pressure, the pulse, the frequency of respiration, and the physical and psychic capacity were observed, it was noted that these functions were not modified by unipolarity of the air ions.

Prognosis of Severe Rachitic Deformities—Alterthum reports the results of after-examinations made in 1927 of twenty-four children who had been born during or shortly after the Great War and who, from 1920 to 1924, had been given intensive conservative treatment in a hospital for an average of 88 months. It was found that extensive retrogression of the visible rachitic deformities had occurred in the cranium, thorax and extremities. Measurements showed that in nearly all the children there was a longitudinal growth deficit corresponding on an average to a year's growth and that the sitting height, the circumference of the head and of the thorax and the transverse diameter at the shoulders and at the hips were too large. These changes in physique in children of early school age are considered characteristic for a previous rickets.

Significance of Organic Acids in Urine During Hunger

—According to Folsold, the elimination of organic acids in the urine during hunger can be stopped almost completely by the administration of free hydrochloric acid. The administration of alkalis, on the contrary, caused a marked increase in their elimination. The organic acids in the urine are for the most part excreted combined with bases. During hunger the amount of bound organic acids remains normal. Therefore even during hunger the excretion of free acid valences by organic acids is slight. The elimination of acids then occurs almost exclusively in the form of phosphates. From the effect of the ingestion of acids and alkalis on the amount of organic acids in the urine it is concluded that they are not always to be considered as a symptom of lowered metabolism.

Choice of Methods of Performing Gastro-Enterostomy A Gridnev —p 3048

Relation of Ether Anesthesia to Pulmonary Complications Following Gynecologic Operations—Stahnke failed to find any relationship between postoperative lung complications and ether anesthesia. Among 3,284 gynecologic operations, postoperative bronchitis developed in 124 per cent, bronchopneumonia in 0.88 per cent, pneumonia in 0.12 per cent. The decade 21-30 gave the greatest number, 141 per cent; the decade 51-60 the least, 81 per cent. Not a single case of aspiration pneumonia developed. The author is of the opinion that the site of the operation is of more moment etiologically than the kind of anesthetic used.

Closure of Gastro-Enterostomy Opening by a Polypus

—In November, 1925, Hammesfahr performed a gastro-enterostomy for pyloric ulcer. The patient did not get well, however, and in January, 1930, a second operation was performed. He remained fairly well until April when he manifested symptoms indicative of obstruction of the gastric outlet. Roentgen examination was negative. In May a third operation was performed. The cause of all the disturbance was a jejunal polypus about the size of a pigeon's egg freely movable, which would slip up into the gastro-enterostomy opening and cause a complete obstruction of the outlet with all the attendant symptoms. The tumor was removed and the patient made a complete and enduring recovery.

Epidemic Meningitis in a New-Born Infant—Mathias reports the case of an infant who died several days after birth. At first the sudden death of the infant could not be accounted for and a necropsy was done. The brain was prepared with a solution of formaldehyde. Thus bacteriologic examination by means of the culture method was impossible. However, pus was detected on the brain stem and on the cerebellum. It was therefore thought advisable to examine the mother for the presence of meningococci. A pharyngeal smear

from the mother actually contained meningococci. The period of incubation is short in meningitis, lasting only from twenty-four to forty-eight hours, and it was assumed that the mother had infected the child shortly after birth.

Hemorrhages into Cervical Portion of Spinal Canal

in the New-Born—Rissmann relates that in a premature infant who died thirty-six hours after birth the necropsy revealed an epidural hemorrhage in the region of the lower part of the cervical portion and in the thoracic portion of the spine. In twenty postmortem examinations of new-born infants, such hemorrhages into the cervical portion of the spinal canal were observed in two cases, and in a supplement to this article a third case is mentioned. It is therefore probable that this phenomenon is comparatively frequent, and it should receive more attention.

Influence of Various Poisons on Sympathetic Nerves

of Heart—Vasilenko's experiments were made on isolated hearts of frogs; the tested substances were dissolved in Ringer's solution. First Ringer's solution alone was perfused through the heart, and the normal cardiac contractions as well as the changes that occurred after stimulation of the sympathetic nerves were recorded. When the cardiac contractions returned to normal the tested solutions were perfused, and the action of the sympathetic nerves was explored. Perfusion of a proprietary chloral hydrate dextrose solution, in 1:200 or 1:300 concentration, soon caused arrest of the heart in diastole; successive stimulation of the sympathetic nerves induced group contractions. In an advanced stage of the poisoning no group contractions appeared in response to irritation of the sympathetic nerves. Then electrodes of an inducing current were applied directly to the heart. An increase of the cardiac contractions, appearing after a short period of latency, pointed to a positive inotropic action of the sympathetic nerves. A positive bathmotropic influence of the sympathetic nerves was ascertained by applying the electrodes directly to the heart with a current below its threshold of excitability. Arrest of the heart following a short increase of the contractions was induced with a 1:1,000 concentration of quinine hydrochloride. In the beginning of the poisoning, stimulation of the cardiac sympathetic nerves brought about group contractions; the contractions were always stronger than those before the poisoning. Application of electrodes to the heart when group contractions failed to appear, elicited a positive inotropic and bathmotropic influence of the sympathetic nerves; the refractory phase appeared notably reduced. Tetrahydronaphthylamine perfused in a concentration of from 1:1,000 to 1:3,000 first caused an increase of cardiac contractions. This was soon followed by a decrease of contractions and arrest of the heart whereby the auricles and the ventricle stopped simultaneously. Stimulation of the sympathetic nerves was sometimes accompanied by group contractions. In an advanced stage of poisoning the electrodes were applied directly to the heart and the contractions of the ventricle were then recorded; the results pointed to a positive inotropic and bathmotropic influence of the sympathetic nerves; there was reduction of the refractory phase. The action of veratrine consisted in the fact that a strong systole of the ventricle was slowly followed by a diastole so that there was one ventricular contraction to two or three auricular contractions. In the advanced stage of poisoning a complete discord between the activity of the auricles and that of the ventricle existed. The effect of veratrine was pronounced only when a 1:10,000 or a 1:20,000 solution was used for perfusion. The solution increased the cardiac contractions in the beginning of the perfusion; irritation of the sympathetic nerves then intensified and accelerated the contractions. In advanced stages of poisoning stimulation of the sympathetic nerves had

no influence on the heart. The effect of the sympathetic nerves appeared when epinephrine was then perfused through the heart. The results indicated that veratrine impairs the conduction of the sympathetic fibers, leaving intact the junctional tissue. The disturbed cardiac activity caused by veratrine poisoning was restored to normal by a perfusion with tetrahydronaphthylamine. The latter accelerated the appearance of ventricular diastole, hence the response of ventricular contractions to auricular contractions increased. The conclusions are drawn that perfusions of chloralose quinine and tetrahydronaphthylamine cause arrest of the heart. The arrest is connected with paralysis of the cardiac automatism whereby the sympathetic nerves remain intact. Stimulation of the sympathetic nerves is able to induce group contractions in the arrested heart in the beginning of poisoning. In advanced stages of the cardiac poisoning when group contractions fail, irritation of the sympathetic nerves exerts a positive inotropic and bathmotropic influence on cardiac contractions in case of a direct stimulation of the myocardium. Veratrine extends the period of myocardial weakness, causes a discord between the activity of the auricles and that of the ventricle and paralyzes the sympathetic fibers. The apparatus reacting to sympathetic poisons (junctional tissue) is unchanged.

Experiments Concerned with Regeneration of Chorda Tympani.—Lisevich's experiments were conducted on three dogs with a fistula in the ducts of the salivary glands. In two of these animals the chorda tympani was severed for the second time. It appeared that the interval between the operation and the beginning of functional restitution of the nerve, compared with that after the first severing of the nerve, was shorter by seven days. The interval between the operation and complete restitution of the nerve was shorter by seven or eight weeks and the interval between the beginning of the restitution and a complete functional restoration was shorter by six or seven weeks. The time required for regeneration of the nerve apparently did not depend on the interval between the first and the second severing, observed up to a year. Thus severing of the nerve appeared to create conditions in the nervous cells promoting proliferation of the fibers on a repeated severing. Moreover, impulses favoring the process of functional restoration may originate in the glandular protoplasm. In one animal the corresponding superior cervical sympathetic ganglion was removed before severing of the chorda tympani. There was evidence that the sympathetic nerve has not an appreciable influence on the time of regeneration of the chorda tympani, on the appearance of unconditioned reflex, on the viscosity of the saliva and on the amount of solid deposit therein. Conservation of a few fibrils of the chorda seemed to prevent the development of a paralytic salivary secretion, while the reflex secretion persisted.

Research on Embolism of Medulla Oblongata.—Veselin induced by means of a gradual embolism of the medulla oblongata paralysis of the respiratory center in dogs and in cats, then the animals were kept alive with artificial respiration. A 1 to 4 per cent solution of sodium chloride containing soot particles was used for induction of the embolism through the carotid. In most of the experiments, both vagus nerves were previously severed. The control animals were treated with curare and exposed to a slow asphyxia by a gradual decrease of artificial respiration; thus phenomena similar to those from embolism of the medulla oblongata were created. Owing to the artificial respiration the animals could be observed for hours. Paralysis of the respiratory center was followed by a pronounced lowering of the blood pressure, sometimes by one or two minutes (reduction of the vascular tonus). On exploration of the reactive ability, the vasomotor center of such animals did not react to asphyxia, to inhalation of carbon dioxide or to injection of lactic acid into the blood. On the other hand the vasomotor center responded promptly and markedly when the induced embolism was considerably increased; the reaction proved to be of mechanical origin. This is the result of lowering of blood pressure in the vessels of the respiratory center. Stimulation of the vasomotor center with chemical substances failed after the respiratory center was paralyzed. The mechanism of chemical excitability of the vasomotor center probably consists in irradiation of excitation from the respiratory center.

- Gonococemia with Gonococcal Endocarditis Case O. Berner—p. 49
- Inductive Research on Larval Heredodysplasia O. Michaelis—p. 411

Keratoses Follicularis Pigment Formation.—Mu reports a typical case of keratoses follicularis (Darier's disease) in which he was able to study closely, for the first time in that disease, the process of pigment formation. In the early stage there is a pathologic stimulation of the pigmentary function, together with increased proliferation. As the characteristic changes in the cells of the malpighian layer become more pronounced the pigment formation becomes correspondingly feeble. The activity of the pigment-forming ferment then decreases markedly and only a small amount of pigment is produced. Along the edges of the overgrowths, the appearance of numerous dendritic cells indicates the process of reparation. The whole development shows that keratoses follicularis produces a marked disturbance not only of the function of keratinization but also of the pigmentary function.

Thallium Acetate Intoxication.—On the basis of experiments on guinea pigs and dogs and clinical observations in ten cases of thallium acetate intoxication in persons with favus or ringworm, Protopchouk et al. state that thallium preparations by their influence on the sympathetic nervous system produce a series of changes in the latter, which in turn act on the appendages of the skin, particularly on the hairs causing disturbances in the vessels of the hair bulbs. Like all other salts of the heavy metals thallium may produce a great many severe disturbances in the organism. In the skin there occur besides falling of the hair, folliculitis and a toxic eruption similar to the ones produced by mercury or bismuth and of a hemorrhagic character with petechiae and ecchymoses. In the mucous membranes besides gingivitis, glossitis and stomatitis (even in its ulcerative form) there occur the phenomena of a thallium angina. These changes may be accompanied by herpetic eruptions and rhagades on the lips, and diarrhea and severe pains in the abdomen. The mucous linings of the stomach and the intestine are hemorrhagic and the latter presents the picture of either desquamative or ulcerative colitis. Other changes noted are hemorrhages and thallium necroses in the liver and nephritis. Acting through the sympathetic nervous system, the thallium preparations may produce the phenomena of transient epileptiform psychosis termed chorea. They may also act directly and produce such phenomena as thallium polyneuritis and disturbances of the blood vessels, including the peripheral vessels of the brain and cerebral hemorrhage. The joints become painful, swollen, tender and crepitant. Fever may be present and the patient may become weak and emaciated.

- *Significance of Intravenous Pyelography in Diagnosis of Renal Tuberculosis I. Hellstrom—p. 836
- *Result of Surgical Treatment of Intestinal Tuberculosis A. Axelsson—p. 847

Posttraumatic Extrapyramidal Injury.—In Melander's patient with known trauma of the right shoulder, and trauma of the head originally considered insignificant by the patient, injury of the extrapyramidal system was indicated by the onset of a paralysis agitans like tremor, marked hemianesthesia of the right upper portion of the body and disordered tonicity of muscles of the right lower extremity.

Intravenous Pyelography in Diagnosis of Renal Tuberculosis.—In the four cases of renal tuberculosis described Hellstrom found intravenous pyelography useful in diagnosis in two of the cases it was of decisive value.

Result of Surgical Treatment of Intestinal Tuberculosis.—Axelsson's material shows that ileocecal tuberculosis is far more amenable to surgical treatment than is tuberculosis of the small intestine. Absolute freedom from symptoms was attained only in those cases of ileocecal tuberculosis in which radical intervention was done.

PHYSIOLOGIC ASPECTS OF OPIUM ADDICTION*

ARTHUR B LIGHT, MD
PHILADELPHIA

The etiology and subsequent events attendant on addiction to opium or such of its derivatives as are known to be habit forming are quite clear. Its continued use will most certainly at some time be followed by a distinct euphoria, so intense that few, if any who have ever experienced it can resist the desire for its return. Attempts to obtain from numerous addicts an adequate description of their feelings and emotions while under the influence of the drug has left much to be desired. "God's own medicine," a term frequently used by Osler, when he prescribed morphine, is a common expression used by the addict. Homer's *Odyssey*¹ contains a sentence which reads, "Whoe'er his wine so medicated drinks, he shall not pour all day the tears down his wan cheek, although his father and his mother both were dead, nor even though his brother or his son had fallen in battle, and before his eyes." Its effects have frequently been described as the bridge between ambition and accomplishment. "It makes you feel as if you were sitting on top of the world," is another favorite description. The nurse about to administer a hypodermic is universally described as an angel from heaven.

Despite the difficulty in ascertaining an adequate picture of the mind under the influence of opium, there is not the slightest doubt that repetition of its use is an effort to regain a source from the realities and hum-drum of life. This objective, when first desired, is obtained from the usual therapeutic doses. The effects last from three to six hours and are followed by nothing more than a return to normality and a vivid remembrance. Its frequent use, however, soon results in two definite departures from the preceding statement, namely, the therapeutic dose is no longer followed by the same intensity of the euphoria, and in turn with its disappearance the normal state is replaced by a definite train of symptoms, so well described in the literature,² known as the withdrawal symptoms. When a person has reached this stage in the use of opium he is described by addicts as "having a habit," or being

"hooked." The continuation of small doses will prevent the appearance of the withdrawal symptoms and maintain the unfortunate one in a comfortable state but lacking the intense euphoria. This procedure, however, is followed by a very small minority, the majority, seeking the "kick" or "thrill," rapidly increase the amounts taken until enormous quantities are reached.

If at any time the drug is abruptly withdrawn, regardless of the amounts used the withdrawal symptoms are inevitable. They reach their height about the end of the third day, then gradually subside, and disappear at the end of ten days or two weeks. With the disappearance of the withdrawal symptoms, tolerance has also disappeared and euphoria can and will be obtained from a therapeutic dose. Recourse to the drug at this point results in the same cycle again, a development of tolerance, a tendency for the disappearance of the euphoria and the return of the withdrawal symptoms following abrupt cessation of its use.

SOMATIC CHANCES

The resultant tolerance to amounts of opium or its derivatives that would prove fatal to nonusers, the intense craving and the constancy of the withdrawal symptoms attendant on the absence of the drug have led to a wide acceptance of the belief that addiction leads to bodily changes that are abnormal and harmful. This view is strengthened by the casual appearance of many addicts who appear shabbily dressed and present a picture of emaciation and general ill health. The fact that many of these unfortunate people are criminals, shrewd and crafty, with no sense of morals has added to this belief. On the other hand, Bishop³ and Kraepelin⁴ recognize the possibility of addicts escaping detection for years, if the general hygiene is good.

One of the first objectives in our studies of the various phases of the opium addiction problem was to find out definitely, if possible the existence of any physiologic or structural changes in patients with addiction of long standing. In all studies to be reported in this paper, the drug used was morphine and except when otherwise stated, was administered hypodermically.

Sufficient morphine was always administered to prevent withdrawal symptoms and to produce drug comfort. In practically every instance, this procedure with a well balanced diet rich in calories, was followed by marked gains in weight. Selecting 100 cases at random a careful physical examination resulted in absolutely negative returns except for scars of previous abscesses the result of infection from hypodermic punctures.

found in about 70 per cent. We were unable to detect a single sign or symptom suggestive of drug action. In many of the patients the pupils were contracted, a few, however, failed to show this condition. Careful measurements of the height and weights showed an average of 0.2 per cent above the normal compared to the average normal weight accepted by life insurance companies. Studies of vital capacities, efficiency tests, heart and circulation, the blood, metabolism, endocrine functions, kidney and liver function, gastro-intestinal tract water balance in fact all the modern clinical tests to determine changes in physiologic function, were carried out in a sufficient number of cases to lead us to the conclusion that addiction to opium or its derivatives does not produce any abnormal or harmful changes in physiologic mechanisms.⁵

In addition to these studies we were fortunate to be able to study a severe case of lobar pneumonia in one addict. Throughout the period of fever, crises and convalescence, a daily dosage of 15 grains (1 Gm.) was administered. The physical signs, clinical chart studies of the blood, character and duration of the illness were identical with that of a severe case of lobar pneumonia in a nonaddict.

TOLERANCE AND FATE OF MORPHINE

The development and existence of tolerance to opium and its derivatives has been recognized for many years. De Quincey⁶ stated that at one period in the history of his drug addiction he used 133 drachms (500 cc.) of laudanum, or approximately 72 grains (4.7 Gm.) of morphine daily. Cognizant of the frequent unavailability of the addict as to the daily amounts used as well as his inability to tell accurately because of frequent adulteration by peddlers, we carried out a series of experiments to test the extent of tolerance in patients before the drug was withdrawn. During the period of administration, careful observations were made continuously on the pulse, respiration and blood pressure as well as on the patient's general condition. One addict received 30 grains (2 Gm.) of morphine intravenously in two hours and twenty-four minutes. At the end of the last injection there was no change in the blood pressure, pulse rate, respiration, chemical condition of the blood or electrocardiographic tracing. His usual dose during this period would have been 4 grains (0.26 Gm.) so that he was tolerant to at least seven times the dose he was accustomed to receive.⁷ Several addicts receiving 15 grains (1 Gm.) of morphine daily were raised to 60 grains (4 Gm.) daily within a period of three to five days without any detectable changes in physiologic behavior or function. These additional amounts did not prolong the absence of the craving.

Proof that this tolerance is still present forty-eight hours after abrupt withdrawal is found in several experiments in which the drug was administered in dosages similar to those given prior to this period. In one addict 20 grains (1.3 Gm.) was administered intra-

venously in fifty-six minutes. Not a single patient showed any significant reaction except immediate relief from the withdrawal symptoms and a return of a feeling of well being.

On the other hand, evidence that tolerance has disappeared following complete cessation of the withdrawal symptoms is based on the death of one of our patients and the collapse of two others, when, following their discharge from the hospital, amounts similar to those used before treatment were again used. The majority of addicts are aware of this change in tolerance, a factor frequently present in the seeking of treatment. It is almost universal on their part to request on approximately the fourth day of their treatment a small dose, usually a quarter grain (16 mg.) to help them from their extreme depression. What we believe they really are seeking is an accurate gauge of their own tolerance. The rapidity in the apparent improvement and enthusiastic endorsement of the treatment that frequently follows the "pick-up,"—the term used by the addict for the quarter grain of morphine—is undoubted evidence in favor of this view. His tolerance is gone, a quarter grain is again sufficient to produce the euphoria. The object of his treatment has been attained.

Studies of the mechanism of tolerance were first inaugurated by Faust,⁸ who concluded from work on dogs that the animal body developed the capacity to destroy increased amounts of morphine, thus preventing damage to vulnerable tissues. Further experiments by Rubsamen⁹ on rats led him to accept Faust's theory in part, but to believe that in addition there must be a certain amount of tolerance developed, as he was able to recover sufficient morphine from tolerant rats to kill nontolerant rats. Terruchi and Kai,¹⁰ confining their studies to rabbits, accept the postulate of increased destruction but finding large quantities of morphine in the muscles and only traces in the liver and brain, attribute to the tolerant body the power of increased destruction, and a mechanism in the muscles that rapidly removes the morphine from the blood and prevents it from attacking the central nervous system.

Our studies¹¹ in this field consisted in the administration of dosages of 15, 30 and 60 grains (1, 2 and 4 Gm.) daily to addicts and the measurement of excretion in the urine and feces. Fecal morphine elimination was very irregular and fell far below that of the urine. In the urine, however, regardless of the amounts administered, we were always able to recover practically 10 per cent of the amount given, that is, 90 per cent was returned or destroyed. Thus there is always the same relationship between the amounts taken and amounts eliminated in the urine. That the 90 per cent is changed into something else than morphine is based on several experiments, where immediately following abrupt withdrawal of the drug only 10 per cent of the last dose could be recovered, and this again within a period of four hours. The end of this rapid decline in excretion coincided with the return of the craving and the appearance of the first signs of withdrawal symptoms.

Similar studies were carried on in addicted dogs in the Laboratory of Pharmacology of the University of Pennsylvania by several members of our staff and practically identical results obtained. In addition, studies of the excretion in normal dogs were made by Wolff, Riegel and Fry.¹² It was found by these investigators that the amounts recovered in the urine and feces from normal dogs was no greater or less than that found in addicted human beings or dogs. Their inevitable conclusion was that tolerance to morphine is not characterized by a significant increase in the capacity to destroy morphine.

WITHDRAWAL SYMPTOMS

The constancy and similarity of the withdrawal symptoms, the extreme variation in intensity, their dramatic disappearance following readministration of the drug and rapid return of a feeling of well being are all features of this phase of the problem that are well recognized. They have in turn been responsible for the controversy that exists concerning the etiology of the symptoms. One group holds strongly to the belief that the whole picture is one of hysteria, similar to the hysteria of the child who is deprived of its toy and is promptly seized with an attack of vomiting. Those holding to the other belief insist on somatic changes due to deprivation of the drug just as there is a failure to burn sugar in the absence of sufficient insulin.

By means of the same methods of study used during the administration of sufficient drug to detect somatic changes, the same addicts were again studied following a period of forty-eight hour abrupt withdrawal and again after readministration and return of the feeling of well being.¹³ The following measurable changes were found: losses of weight ranging from 3 to 15 pounds (1.4 to 6.8 Kg.), concentration of the blood, and a polymorphonuclear leukocytosis in 60 per cent of our cases in one case reaching 28,000 per cubic millimeter. All other tests were negative, including tests of physical fitness, despite the fact that the addicts complained of extreme weakness. Following the return of well being after morphine was again administered the loss of weight was still present, the blood concentration was unchanged, and in those cases in which a leukocytosis was present the total number of leukocytes had actually increased, the person showing 28,000 now reaching 30,000. Despite the fact that the addict again professed to feel well and strong the tests of physical fitness showed a poorer response.

Studies¹⁴ in water balance, checked with a similar study on normal persons, led us to the conclusion that the loss of weight was due in a large degree to the failure on the part of the addict to take food and water during the period of withdrawal together with a degree of restlessness. This undoubtedly accounts for the blood concentration as well. Neither the blood concentration nor the leukocytosis can be held as responsible for the state of ill being as both these changes were still present following the readministration of the drug and the return of the state of well being.

The intensity of the symptoms can certainly be controlled by the addict himself, even to the degree at which they are scarcely perceptible. One addict under going treatment in our ward appeared to suffer intensely and exhausted our patience to the utmost. A year later, when he was arrested as a shop lifter and known to be addicted again the police surgeon was unable to detect any withdrawal symptoms except a slight diarrhea. The addict was well aware that, could the charge of drug addiction be substantiated, he would face an additional sentence.

This is but one of numerous experiences which have led us to the belief that addicts will and can control to a large degree the intensity of their withdrawal symptoms. This factor together with the largely negative results obtained in our studies of the withdrawal symptoms lead us to believe that they are frequently complicated by hysteria and that further studies should be combined with psychiatric and psychologic investigations.

3815 Chestnut Street

TREATMENT OF DRUG ADDICTION *

ALEXANDER LAMBERT, M.D.

NEW YORK

To confine drug addiction only to the habitual use of opium derivatives is too narrow a conception. It is really the habitual use of any drug for the purpose of avoiding emotional strains of life.

In its mildest form it is manifested by the habitual taking of the hypnotic group of drugs, in its more intense narcotic forms it is seen in the excessive use of alcohol or of the opium alkaloids. The causation is the same in all instances the difference being only one of degree the psychologic demand being for forgetfulness of life's worries, or even the obliteration of all consciousness to escape the misery and unhappiness of existence.

It is immaterial whether custom and public opinion condone alcoholic drunkenness and condemn morphine addiction, the basic principle of causation for the two is the same.

The mildest form of drug addiction to dodge the unhappiness and unsolved problems of life is the use of the hypnotic group. Formerly chloral was used today it is usually some one of the many members of the barbituric acid group.

Chloral taken alone, or mixed with bromides, produces its harm by causing an inaccuracy of mental judgment and even delusions and distortions of outlook. The bromides although usually thought harmless produce a distinct delusional psychosis when taken to excess. The danger of the barbituric acid group is that perversion of personality which frequently occurs in those who take them in the usual hypnotic doses. The mildest exhibition of this is seen in the perversity and resistance of these patients. They prefer to say the mean and sharp thing rather than to be agreeable, they are antagonistic to all suggestions they are suspicious, ill tempered, selfish and cranky, and they cause a great deal of unhappiness and misery to themselves and to others.

The great majority, however, of recurrent morphine addicts today are found among constitutionally inferior personalities, the so-called inadequate psychopathic group. In the work of the Mayor's Committee on Narcotic Addiction in New York City in the last year, it was found that 87 per cent of the 318 addicts coming under their care for study were of this inadequate psychopathic type, 42 per cent tended toward the dementia praecox type. There were also the types of criminalism, of nomadism, and of manic-depressive tendencies, but there were only 13 per cent who seemed to possess the average stabilized personality designated as normal. These inadequate personalities are not necessarily inadequate in their intelligence. They vary, of course, in the degree of their emotional sensibilities and their emotional reactions. Their intelligence does

Chart 1—In this and the accompanying charts *A* indicates gastro intestinal symptoms consisting of nausea and vomiting abdominal cramps and diarrhea *B* muscular discomfort aches and twitches *C* restlessness mental and physical with increased psychomotor activity *D* prostration (subjective and objective weakness). The charts are redrawn from charts used in the report of the Mayor's Committee on Drug Addiction New York City 1929. In this chart the sections at the top present a comparison of four major withdrawal symptom groups (*A B C D*) under Narcosan solid line Narcosan broken line control. Below is a composite graph of the four major symptom groups solid line Narcosan sixty eight cases broken line control sixty eight cases average of 100 controls in all the charts *a* indicates period on morphine which was stopped and treatment begun as indicated by heavy vertical line.

Alcohol is thus more frequently used than morphine. It can be used to its full narcotic power, then set aside, and used again when memories are too unhappy. It is

not control their actions and their actions are based on the emotional impulse and remain uncontrolled by their intelligence however clever their degree of intelligence may be. They are not legally insane, but they show the same anomalies in their mental make-up as the insane. They differ only in degree, and they form the most trying problems of today in their proper care and treatment.

The recent work of Torrance and Light in Philadelphia has shown conclusively that there is no such

Chart 2—Above comparison of four major withdrawal symptom groups under atropine solid line atropine broken line control. Below composite graph solid line atropine twenty five cases broken line control twenty five cases, average of 100 controls

thing as an addiction disease, their work has shown that the physiologic processes in the bodies of those addicted to morphine do not vary from the average conditions found in nonaddicted persons. Their investigations under the New York Committee for the Study of Drug Addiction also showed that there were no physical neurologic changes found in these addicts. These apparently negative results are of the highest value, as they are the positive scientific evidence that an addiction disease produced by morphine does not exist. This fallacy had taken such hold of both the lay and the medical mind that the work of these men cannot be too strongly praised for its value in clearing up a much mooted question.

The work of the Mayor's Committee on Drug Addiction in New York City was undertaken to test the best method of treatment of the morphine addicts. The work formerly done in the penitentiary on Welfare Island in New York in the treatment of these addicts by Narcosan was continued. This work had been done without sufficient control. We believed that our knowledge of the symptoms of the withdrawal of morphine was sufficient to be used as a control. We had heretofore always controlled the withdrawal symptoms by codeine and did not realize the definite limitation of the withdrawal symptoms to from seventy-two to ninety-six hours' duration. From the results of our recent work in Bellevue Hospital on the Mayor's Committee, it is evident that this view had been an error of judgment, and the careful, strictly controlled observations of the Mayor's Committee have shown accurately the value of the various methods of treatment and of the drugs used in the treatment of morphine addiction.

In the accompanying charts all observations have been translated into curves showing the intensity and duration of the various symptoms during withdrawal

of morphine. It is evident from these curves that the withdrawal symptoms of morphine are self limited to from seventy-two to ninety-six hours.

One hundred patients were treated as controls. Narcotics were not given unless a patient was threatened with a serious collapse during his withdrawal period, sterile water, containing a little glycerin and colored with a few grains of bismarck brown to make it the same color as the Narcosan solution was given and neither the nurses who gave the injections, nor the patients themselves, could tell whether a control solution or the medication was being given. The injections were run parallel, and this removed from the patients all sense of fear that they were not receiving some narcotic treatment and definite medication. This enabled us to judge the reactions following the treatment as being the real withdrawal symptoms. The work on Narcosan thus strictly controlled was continued.

Scopolamine and atropine were also tested in a similar manner since these two drugs form the basis of nearly all treatments for morphine withdrawal. The reduction treatment of morphine was also taken up, in which no drug treatment was used, but the morphine gradually but surely reduced. A short experimentation followed with the use of codeine to relieve the symptoms of withdrawal of morphine. All these separate tests required time in a small ward, with but few patients at any one time. But with strict control, perfectly accurate estimates were obtained. The symptoms were divided into four classes: (1) the gastrointestinal group, with nausea, vomiting, abdominal cramps and diarrhea, (2) muscular discomfort with aches and twitching, (3) restlessness, mental and physical, and increased psychomotor activity, (4) prostration, with subjective and objective weakness.

Chart 3—Above comparison of four major withdrawal symptom groups under scopolamine solid line scopolamine broken line control. Below composite graph solid line scopolamine twenty five cases broken line control twenty five cases, average of 100 controls

The accuracy of the observations was carefully checked, one man alone judging the symptoms and another man deciding which patient should be a control and which should receive the treatment under observation. The nurses in charge did not know what treatment was being given.

The results of the treatment show that the gastrointestinal symptoms under Narcosan are much increased over the controls, muscular discomfort with aches and

twitching comes earlier with the use of Narcosan, rises higher, and then diminishes equally with the others, the restlessness is practically the same with Narcosan as in the controls, the prostration during the entire treatment is slightly more noticeable under Narcosan than in the controls

The next drug to be tried as a treatment was atropine. It is evident from the curves that those receiving atropine show about the same intensity of symptoms as the controls but that the recovery from their symptoms is prolonged, and that they recovered more slowly from their symptoms under atropine than did the controls. The gastro-intestinal reaction is less severe under atropine, the muscular discomfort is not quite as severe but lasts distinctly longer, restlessness, however, is more intense under atropine than in the controls, and prostration occurs more quickly, and, while not more prolonged is slightly more intense.

Under scopolamine it is evident that patients suffer more than the controls, their suffering does not begin as soon, it rises to its climax at the end of forty-eight hours of treatment, and the gastro-intestinal symptoms are markedly increased under the scopolamine. Muscular discomfort is practically the same as in the

Chart 4—Above comparison of four major withdrawal symptom groups during seven day reduction solid line seven day reduction broken line control. Below composite graph solid line seven day reduction twenty five cases broken line control twenty five cases average of 100 controls. Vertical line marked b shows end of seven day reduction.

controls, and their restlessness and delirium and mental and physical activity are enormously increased under scopolamine, as well as is their prostration, which is more intense in all periods of the treatment, beginning earlier, and lasting considerably longer. These results agree with our previous clinical experience, that patients being taken off morphine under the scopolamine treatment suffer for days, or weeks, from a bodily and mental exhaustion that is one of the most marked features of the treatment.

A seven-day reduction of morphine was tried in which the patients, as compared with the controls, suffered materially less. But while their suffering was less intense it was more prolonged, and at the end of the seven days, when they were cut off their drug, the withdrawal symptoms flared up acutely, but with marked diminution in intensity in all patients. The patients, however, were less easy to care for, they were irritable, mean, more quarrelsome, and more difficult in every way to manage. It is interesting that after the morphine was cut off from these patients, as the curve shows, they still had about seventy-two hours of increase of symptoms.

In a fourteen-day reduction, it is noticeable that the gastro-intestinal symptoms are reduced to a minimum, the muscular discomfort, however, increased, with a rising curve toward the day on which morphine ceased to be given, at the end of two weeks, and then flared up for forty-eight hours and rapidly diminished, restlessness was diminished in comparison with the controls, but in a rising curve, until it also disappeared, prostration shows a similar curve, but to a less degree.

The next method of treatment was an endeavor to ascertain to what extent codeine would control the withdrawal symptoms of morphine. Our clinical experience had taught us that codeine does control them and that it is so rapidly discharged from the body by the kidneys that it is not stored up as long as morphine, nor does it possess the narcotic value to the human organism that morphine does. It produces sleep, it alleviates pain to a marked degree, but that curious narcotic value it does not possess, and codeine habits are exceedingly rare. In 1,700 patients in private practice, treated for many different narcotic addictions to the various habit forming drugs of the opium group and the hypnotic chemical group, it was found that only ten of them were addicted to codeine, and these had required it through their endeavor to alleviate pain.

In those receiving rapid reduction with codeine, the curves show that at the end of the week, when the morphine was cut off, there were the regular three days of increase of symptoms after the codeine was also cut off, but these symptoms do not rise as high as those in the fourteen-day reduction, nor as high even as the symptoms after a seven-day reduction.

Since these experiments have been carried on at Bellevue, it has been found in private practice that if the codeine is continued a few days beyond the morphine and is tapered off rather rapidly, that is, in four or five days, the symptoms are reduced to a minimum, although there is a sense of irritability and restlessness. Even that is of little consequence compared with the usual withdrawal symptoms. In other words, the withdrawal symptoms do not go beyond the intensity of the disagreeable restlessness produced by the cutting off of any narcotic. The gastro-intestinal symptoms disappear, the muscular discomfort is at a minimum, the restlessness is the most marked of the symptoms, but that soon ceases. It is evident, therefore, that codeine is the only drug we have as yet found that really modifies materially and successfully the withdrawal symptoms of morphine.

The best method of giving this treatment is to calculate the amount of morphine, in terms of Magendie's solution, that a patient is taking in twenty-four hours and then for a ten-day reduction, diminish the morphine each day about one-tenth. As the morphine is best given at four hour intervals, and there are six doses a day, the total daily amount is again divided by 6, and the amount of reduction is easily calculated in the number of minims of Magendie's solution. For instance, if the patient is taking 4 grains (0.26 Gm) a day the equivalent to 120 minims a day of Magendie's solution, he is taking 20 minims every four hours, if he is to be reduced 12 minims a day, he is reduced each day at each four hour dose 2 minims of his Magendie's solution, in this way in the ten days his Magendie's solution is brought down to zero.

But at the same time that his morphine is reduced, the codeine is increased from the second day beginning at $\frac{1}{2}$ grain (0.03 Gm) every four hours the first codeine day, then 1 grain (0.065 Gm) every four

hours the second day, then 3 grams (0.2 Gm) every four hours the third day, 4 grams (0.26 Gm) given every four hours the fourth day, and 5 grams (0.3 Gm) every four hours the fifth day, continued at 5 grams every four hours until three days after the last dose of morphine has been given when it is tapered off as rapidly as the discomfort of the patient permits. It is wise to use the codeine phosphate because of its greater solubility, and if the codeine solution is made up in the same form as Magendie's solution it is easily accessible

Chart 5—Above, comparison of four major withdrawal symptom groups during fourteen day reduction solid line fourteen day reduction broken line control Below, composite graph solid line fourteen day reduction twenty five cases broken line control twenty five cases Vertical line marked b shows end of fourteen day reduction

and desired amounts can be given every four hours simultaneously in the same syringe as the Magendie's solution. In this way the patient does not know when the morphine ceases to be given to him. If this amount of codeine is not sufficient, extra doses of codeine can be given without harm to the patient or to his reduction treatment. This large amount of codeine is apt to be very constipating, and the patients should receive the amount of cathartic necessary to keep their bowels in good action, severe purging is not necessary under this form of treatment, and it is apt to irritate the gastro-intestinal tract. Of course, the patient's intestinal tract should be thoroughly cleaned out before the treatment is begun, it is also wise to test out the patient for the first twenty-four or forty-eight hours of treatment with the amount of morphine that the patient says he is taking, to see whether or not he is comfortable.

The advantage of this codeine and morphine treatment is that since the patients suffer so little there is no occasion for deception, there is no question of a defense reaction for fear of suffering, they get away from their drug without the irritability and fear of suffering that the abrupt methods and old forms of treatment give them and they are quite manageable.

Of course if one is dealing with patients who do not want to recover, who do not want to be taken off it one is dealing with a large mass of psychopathic addicts with inadequate personalities who make no attempt at reconstruction, one will encounter every sort of deception and every known form of resistance and lack of cooperation. But in private practice with those who have been caught in the toils of the narcotic habit through legitimate medication or through the existence of pain, this treatment is easily administered in a hos-

pital and the patients can easily be taken off their narcotic.

All morphine patients, after they are once off, should be reconstructed physically as well as psychologically, and the best method of accomplishing this is through physical exertion exercise or work. While building up into good physical condition, the sooner they are occupied with the rearrangement of their psychologic distortions, the better and the more quickly they will be able to face existence cheerfully without their drug.

Sleep comes to addicts gradually during their period of treatment, and in the restless period of the few days as their morphine is cut off, or then codeine diminished, hypnotics are very difficult to administer. Sodium amytal and practically all members of the barbituric acid group, if given in sufficient amounts really to make patients sleep and to influence at all the withdrawal symptoms, must be given in amounts that poison them, and in the endeavors to obtain sleep for these patients the poisoning from the various hypnotics given even to the point of delirium, has been a noticeable feature. It is harmful, in my opinion, to push hypnotics as far as this, it only adds to the poisoning of the patient, and does not relieve the withdrawal symptoms but adds to the difficulties of handling the situation.

Chloral from 25 to 30 grains (1.6 to 2 Gm), with codeine 1 or 2 grains (0.065 or 0.13 Gm), tincture of hyoscyamus, 30 minims (2 cc), is a very useful hypnotic for these patients, but even this cannot be continued too long. Patients must be made to fight out their lack of sleep by endeavoring to read, or by taking hot baths, or applying hot packs, all of which will relax them. They gradually obtain more and more sleep each night and if they can be made to take tonic baths in the day time or physical exercise, they can, through exertion obtain their sleep more quickly than otherwise.

The question is often asked: What can be done for the inadequate group of personalities that form the

Chart 6—Above, comparison of four major withdrawal symptom groups under rapid reduction with codeine solid line rapid reduction with codeine broken line control Below, composite graph solid line rapid reduction with codeine twenty five cases broken line control twenty five cases Vertical line marked b shows end of treatment by means of rapid reduction with codeine

ever recurrent narcotic addicts in the penal institutions? It is only through forced confinement, learning some trade and working at some definite occupation that these patients can be trained and reconstructed. Occupational therapy in forced confinement is the best solution. This will slowly regenerate a larger number than can otherwise be restored. If at the same time in

endeavor is made to take these patients individually to reconstruct their distorted mentalities and twisted views of life, a great deal can be done to diminish their number. But this is a problem that should be undertaken by the state, just as the state today undertakes the care of the mentally diseased. These individuals, to be regenerated, should be treated as unable to lead a normal existence, not as if they were in a boarding house for permanent care but as though they were mentally ill and must be reconstructed through persistent treatment.

It is at present hopeless to attempt to take care of certain individuals among drug and alcoholic addicts without the power to deprive them of their liberty and force them through institutional care and reconstruction to reorganize themselves and their mentalities. This at present the law does not permit, but, until it is done, many inadequate personalities will continue to seek their peace of mind in narcotic addiction.

43 East Seventy-Second Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LIGHT AND LAMBERT

DR. WILLIAM H. MAYER, Pittsburgh. The neuropsychiatrist views the morphine addict much as many other things that happen in his experience. The failure of individuals to succeed in the matter of spiritual comfort and to be content with the reality is relative. I refer to this because of the type of case mentioned by Dr. Light, particularly the individual who does not look forward to excess but is content with a small dose of morphine to assist in his adjustment. As has been clearly shown in a former study, to which Dr. Lambert has also referred, the question of addiction disease is a matter of conjecture. I believe that all the proof is that there is no addiction disease. I intended to take issue with Dr. Lambert at times when he compared alcoholic and morphine addiction as a common type. Our group insists on making discriminations a little finer, although, in the main, one must agree with the broad principle that reality and flight therefrom governs both habits. One practically never sees the stage of tolerance in alcoholism that unquestionably occurs in a morphine addiction. It is possible that the somatic changes in alcoholism which are not seen in morphinism are responsible for the failure of elimination and also explain lowering of tolerance in the alcoholic addict, which is never seen in the morphine addict. What Dr. Lambert said concerning treatment is true. I went through the narcozan period and there became acquainted with the fact that withdrawal symptoms were largely emotional reactions, and suggestion controlled many of the cases. Actual collapse occurred in some cases, but I am willing to believe that similar collapses occurred from other causes than from physiologic changes pursuant to the withdrawal of morphine. There is another group, which includes those suffering from periodic pains of true tabes dorsalis, who have received arsphenamine and yet have obscure crises of pain relieved only by morphine. Once removed from the habit and free from the pain, there was no effort made to take the drug. With the recurrence of the pain, another cycle of morphine habit was begun. A considerable percentage of morphine addicts examined by spinal puncture give interesting observations to support the belief that this group exists. As Dr. Light points out these individuals become enamored with the feeling of euphoria and proceed to use the drug in order not only to be free from pain but to enjoy a state of lethargy, but this is only a specter, and the moral collapse that occurs is due to the social experiences surrounding the drug habit.

DR. G. WILSE ROBINSON, Kansas City, Mo. I am glad the authors have included in this discussion other forms of drug addictions besides morphinism and alcoholism. There are various reasons why people use alcohol, narcotics and sedative drugs excessively. The matter of maladjustment has been mentioned. The majority of those who use drugs and alcohol to excess do not meet well the realities of life. Many of those

who use alcohol excessively are subject to attacks of mental depression—a mild form of manic depressive psychosis. We all, more or less, crave the experiences, sensations and the thoughts of our childhood, during our childhood experiences we have autisms and fantastic thoughts, we have ideas that carry us beyond reality. We crave that in our adult life. Those people, especially introverts, who do not meet realities well seek that situation by morphinism and alcoholism, it gives them the autism and fantastic thoughts of childhood and helps them to banish the realities of life, which may be very painful to them. Morphine and alcohol are sedatives that act especially on the small pyramidal cells of the cerebral cortex, they alter the thought processes. The urea preparations, of which barbital and phenobarbital are the best known and most widely used, have a different action. They act on the brain stem and mid brain, on the thalamic centers and the thalamic motor areas. In 1909, Dr. Lambert published what has been known as the Lambert treatment. I tried it out and the results were so satisfactory that I have used the treatment regularly since that time. I have tried many other forms of treatment for alcoholism and morphinism but have never been able to find a treatment that works so well. I have used it on patients of all ages and degrees of physical condition, without harmful effect. Aged patients and those who have used large quantities of morphine for many years respond well to this treatment.

DR. ALEXANDER LAMBERT, New York. I would like to mention the difference between the action of codeine and the action of morphine for the alleviation of pain. Codeine, if it is used with the analgesics, I mean acetphenetidin and either acetylsalicylic acid or sodium salicylate, and then using sodium bicarbonate with them, is one of the best forms of medication that I know to stop pain. Patients can be carried through their various forms of crises without the use of morphine and they do not acquire a habit with codeine. In about 1,700 cases of all kinds of habits, I found that in only ten of those patients was codeine used as a habit per se with which to relieve the pain. It does not have the narcotic value that morphine has. It is eliminated rapidly by the kidneys. It is methyl morphine and does not combine with the nervous tissues as the ethyl radical does. It is a most useful drug, especially combined with those analgesics, and it should not be included in the habit-forming drugs. It is because it comes from opium that it is so classed. That is the lay point of view, which is difficult to change. But it does not have that peculiar narcotic value and can be used with the greatest benefit in combination and in tiny doses or in big doses, as the case may be, depending on the individual. The treatment Dr. Robinson mentioned is useful if the staff can be trained to give it definitely and not make mistakes. It is full of details. If understood well and manipulated well, with intelligent nurses that one can hold and keep and train in one's own institution, it can be manipulated better than anything else I know. It has given me excellent results. But if all these conditions cannot be obtained, I have found that the reduction with codeine seems to answer the same purpose and it can be given by a routine hospital treatment. It seems at present to be the best available.

The Revival of Heliotherapy—Worship of the sun was known to the ancients long before the Christian era and was practiced not only by the barbarian races but by cultured Egypt. We are told that the father-in-law of Tutankhamen gave up other gods for the worship of the Sungod Ra and built a new city and temples to his honor. The Greeks and Romans, while not worshipping the sun, understood its health giving properties. Hippocrates practiced heliotherapy on the island of Cos in the fourth century B. C., and from 130 to 200 A. D. it was practiced at Rome by Celsus and Galen. Cicero has described for us the solarium built at the villas outside Rome. The solarium was usually a flat terrace or roof designed to trap the maximum of sunshine. The Druids in our own islands were also sun worshippers. The cult of the sun was apparently regarded as pagan for with the advent of the Christian era sun worship fell into abeyance. It is only comparatively recently that its value has again been recognized—MacCarvill, Patrick. Ultraviolet Light, X-Rays and Radium as Therapeutic Agents, *Irish J. M. Sc.* February 1931.

BLADDER DIVERTICULA

WITH ESPECIAL REFERENCE TO THEIR
SURGICAL REMOVAL *

J S EISENSTAEDT, MD

AND

T G McDOUGALL, MD

CHICAGO

A diverticulum of the bladder is a cavity in closest relation to it produced by a localized dilatation of its wall. Diverticula are characterized by a definitely circumscribed opening which represents the connection between the cavity and the bladder, and by a mucous lining which is continuous with that of the bladder.

Vesical diverticula have been classified into various groups: congenital and acquired, true and false, solitary and multiple, and traction diverticula. They have been divided into those of the dome, of the lateral walls, and of the floor of the bladder.

Some authors have grouped these sacs as congenital and acquired, basing the division on the layers present. Klebs,¹ Englisch² and Rokitsansky³ stated that the presence of all layers of the bladder wall designated a diverticulum of congenital origin, while in the acquired type there was merely a prolapse of the mucosa between the muscle fibers. Hinman⁴ states that the classification of Englisch and Rathbun⁵ into true and false diverticula cannot be made, and he believes that they are all acquired. Kneise⁶ says that the overwhelming majority are surely not of congenital origin, and that at most the anlage for their formation is present in embryonic life. He stresses the fact that the weakness in the muscularis is a site of predilection for the formation of diverticula. Thomas states that at least 80 per cent are acquired through some obstructive process. Opposing this opinion, Lower considers most of them congenital.

Embryologic studies by Keibel,⁷ Reichel⁸ and Retterer⁹ afford at the most only suggestive hypotheses. The experimental work of Rose showed that diverticula are congenital to the extent that a loose fibrous pathway must be present through the bladder wall before the acquired factor, namely, a raised intracystic pressure, can herniate the mucosa. Lowsley and Gutierrez¹⁰ state that "it would seem, therefore, that there is a possibility that vesical diverticula are primarily congenital, although there is a greater likelihood of their manifestation during late adult life, which may be due to the occurrence of factors inducing abnormal tension within the bladder."

Herbst and his collaborators, as a result of numerous experiments on dogs, state that "increased intracystic pressure during micturition such as may be produced by spasmodic contractions of the detrusor muscle due

to infection or other causes of increased muscular irritability is a third factor which evidently plays an important role in the formation of diverticula." They were apparently first to emphasize the importance of infection in the production of these sacs in persons in whom obstruction alone had not done so.

Most diverticula are acquired, but they occur at a point of congenital weakness of the bladder wall through which herniation may occur if one or both of the acquired factors operate. The openings of most diverticula are located in the vicinity of the ureteral orifices. Hinman found the openings of 98 of a series of 135 solitary diverticula and 25 of a group of 28 multiple sacs in this neighborhood. Diverticula not infrequently occur at the site of the urachus. Those involving the posterior wall of the bladder are uncommon, but those of the anterior wall are rarest of all.

Diverticula vary in size from one containing but a few cubic centimeters to cavities containing several cubic decimeters, and they may greatly exceed the size of the bladder itself. Potherat¹¹ reported a case in

Fig. 1 (case 1).—Anteroposterior cystogram showing indistinctly presence of diverticula.

which the diverticulum contained 5,500 cc and Warren-Green¹²—one containing 3,700 cc. The size of the orifice varies considerably and bears no relation to the size of the sac itself. Formerly, it was thought that the orifice of a congenital diverticulum had definite characteristics but this does not seem to be true.

Vesical diverticula may have various shapes, those most commonly seen are round, ovoid, finger-like or bizarre, depending often on conglutination between the sac and the surrounding structures. They are usually solitary, but 10 per cent of cases reported presented multiple diverticula. As many as seven have been recognized in one patient. The two sides of the bladder are about equally affected. In 88 per cent of vesical diverticula observed in men, the bladder was trabeculated, evidencing overwork from an obstructive process.

The relation of the surrounding structures to the diverticulum is extremely important from the point of view of surgical removal. Adhesions may bind them

to important intra-abdominal organs or to large blood vessels.

The ureter may empty into the diverticulum, as in one of our cases but this is a rare occurrence and a special technic is required for the removal of such a sac. Hinman in 1919 reported but fourteen cases from the literature, including two which he himself had observed.

Fig. 2 (case 1)—Lateral view of same case showing moderate sized bilateral diverticula

The conglutination between the ureter and the diverticulum results from the increase in size of the diverticulum. The ureter is pulled in its long direction and its lumen is narrowed or markedly displaced. As the diverticulum enlarges, the ureteral orifice becomes further away from the opening of the diverticulum.

PATHOLOGY

The walls of the diverticula in the series here reported uniformly show all layers of the bladder wall, however, with certain changes which may best be described by quoting the pathologists report of typical cases. 'In general, the sections showed the following changes. Some of the sections still showed transitional lining cells, which in some fields were apparently hyperplastic. A few sections showed metaplasia of the lining cells. The mucosa and submucosa as seen in most of the slides were infiltrated by lymphocytes, endothelial cells and occasional polymorphonuclear leukocytes and a few plasma cells. There was a varying amount of connective tissue combined with a new formation of small blood vessels. Other sections showed islets of muscle fibers in the walls of the diverticulum. Some of these fibers were atrophic.'

The thickness of the wall depends almost entirely on the degree of inflammation present. Sacs which have been the site of infection are much thicker than those in which the inflammatory reaction has been mild. However, as a result of stretching, the walls may become quite thin and in fact may perforate. This thinning is evidenced by flattening of the lining epithelium of the mucosa.

The muscular coats may become greatly thinned and in places entirely lacking or merely show microscopically the remnants of muscle fibers. This extreme thinning of the musculature is especially noted in the fundus of the diverticulum.

The changes in the epithelial lining are due partly the stagnation of urine, the cells become saturated; subsequently loosened.

Leukoplakia of the lining of a diverticulum has been reported by Blum.¹³

Infection of a vesical diverticulum deserves special emphasis as usually the first symptoms manifest themselves when infection has occurred. It is readily seen that the physical characteristics of diverticula make them a site of predilection for infection. The practical impossibility of overcoming or curing the infection, once it has taken place, is obvious for the same reason, viz the position of the diverticulum, its relative narrowness, and the contractions of the orifice.

The source of the infecting bacteria is not at all easy to determine, as is the case in many urinary infections. Likely sources are the prostate, urethra, rectum and instrumentation. Hematogenous infections occur. The diverticulum may become infected from the bladder or vice versa. English and others have reported isolated infection of a diverticulum. This observation, we believe, would be very difficult to prove, and if this phenomenon does occur, it is purely of academic interest. Severe infections may occur with phlegmonous processes in the wall of the diverticulum, leading to perforation into the peridiverticular tissues and occasionally into the peritoneum (English).

Chronic infection always produces an inflammatory reaction in the neighborhood of a sac, and produces

Fig. 3 (case 2)—Anteroposterior cystogram showing diverticulum in which right ureter emptied

adhesions of varying grades and character, later becoming very fibrous.

Associated is the presence of stone or tumor within the diverticulum, instances of which are not uncommon. We have observed one case in which the stone projected from the diverticulum for approximately 2.5 cm, and

¹³ Blum, V. Chirurgische Pathologie und Therapie der Harnblase Divertikel. Thieme 1919.

the part within the sac was somewhat larger than the protruding portion. Similar stones have been diagnosed as encrusted carcinomas of the bladder. The presence of stones complicates the situation because they occur in the more severely infected cases. Occasionally a decubitus ulcer of the wall ensues with the increased possibility of perforation, and usually more marked adhesions are present. Tumors that have been found

Fig. 4 (case 2) —Lateral view of same case showing relative size of diverticulum

within diverticula are angioma, papilloma, sarcoma and carcinoma.

The symptoms of vesical diverticula are not characteristic and usually appear merely as disturbances of urination depending on the associated pathologic changes as they have been outlined. They are usually symptomless unless infected.

Not infrequently, functional disturbances of micturition occur because of changes in the musculature of a large diverticulum.

Dysuria of an intermittent course for a long period of years is a suggestive symptom. The presence of a diverticulum may be suspected if, after the bladder has apparently been washed clean, definite turbidity of the irrigating fluid suddenly appears. The necessity of emptying the bladder twice in a short time may be regarded as a suggestive symptom. Retention of urine can occur from a diverticulum compressing the vesical neck.

Bleeding as a result of infection, ulcer, stone or tumor within a diverticulum may be noted.

Strangury, dribbling, incontinence and a sensation of not having emptied the bladder may be present but have nothing characteristic in their occurrence, associated symptoms or sequence. Occasionally a patient will state that he can void only when assuming unusual positions or with the assistance of external pressure. This phenomenon is likewise not characteristic as it

may occur in the presence of vesical stone or prostatic hyperplasia in the absence of a diverticulum.

The diagnosis of bladder diverticula cannot be made by obtaining a characteristic history of the condition, as this does not exist. The subjective symptoms are so indefinite as to be entirely untrustworthy.

The diagnosis is properly made by cystoscopy and is confirmed and augmented by cystograms. The orifice of the diverticulum is readily identified and its relative location can be determined by cystoscopy alone. Occasionally the beak of the cystoscope can be introduced into the sac itself and all characteristics of the cavity can be noted. The passage of a shadowgraph catheter into the sac is of great value at times, and often a considerable length of the catheter can be coiled in the diverticulum. Roentgenographic studies then made will give an excellent impression of the size and relations of the sac. A series of cystograms affords the best method of accurate diagnosis, especially in those cases in which cystoscopy is impossible or difficult. The details of the technic of cystography will not be here described, but the complete technic as described by Blanc and Negro¹⁴ will produce valuable roentgenograms which will afford accurate diagnosis of the size, shape and position of the sac. Intravenous urography will undoubtedly disclose many unsuspected vesical diverticula and should be especially valuable in examining cases with infection in which instrumentation may be dangerous. Roentgen exposures of the bladder area should be made in the lateral and semilateral as well as the supine position. Stereoscopic films are often of additional value.

TREATMENT

Nonsurgical procedures are of little value in the treatment of diverticula and should be employed only

Fig. 5 (case 3) —Lateral view of bladder showing coiled shadowgraph catheter in diverticulum, stone in bladder lying horizontally and large stone in lowest portion of ureter lying vertically.

when operative intervention is definitely contraindicated by the poor general status of the patient, in which cases the prognosis of radical resection of the diverticulum offers too great a risk.

Judd¹⁵ states that "those who have had the most experience with these cases seem to be unanimous in

14. Blanc and Negro. La cystographie. Paris: Masson & Cie 1926.
15. Judd, E. S. Diverticula of the Bladder. Ann. Surg. 68: 197 (Sept.) 1918.

the feeling that the proper treatment for any of these diverticula is complete excision of the sac, and that any treatment less radical will not be satisfactory. Our experience bears this out."

OPERATIVE TECHNIC

Operation for diverticulum of the bladder in those cases in which operation is definitely not contraindicated

Fig. 6 (case 3)—Anteroposterior cystogram of same case showing diverticulum. Both stones are obscured by filling fluid

should include the complete surgical excision of the sac or sacs and also removal of the source of the obstruction, usually at a later period, depending on the status of the patient and the nature of the obstructing process

Fig. 7—Section showing isles of muscle fibers surrounded by connective tissue. One part shows a rather dense infiltration of lymphocytes, very few endothelial cells and an occasional leukocyte

The surgeon operating on a vesical diverticulum should have definite knowledge of all possible circumstances regarding the particular case at hand. We refer particularly to the number, size, location and relations of the diverticulum. Even then, it may be necessary to modify the intended technic on account of circumstances first manifesting themselves during the course of the

operation. Without attempting to discuss the merits of the various methods employed, we have been uniformly successful in completely resecting the sac in all cases attempted by the following technic, with necessary modifications, depending on the individual peculiarities of the case.

Spinal anesthesia has been used in the more recent cases of the series. The relaxation obtained by this method of anesthesia, and the collapse of the intestines, making it unnecessary to hold them back forcibly by retractors or other means, combined with the more moderate type of the patient's respirations, as compared with those during any method of inhalation anesthesia, have contributed in our opinion to the ease and relative safety of the operation.

A moderate to extreme Trendelenburg position was used in all cases. Preliminary drainage of the bladder by catheter or suprapubic tube has not been used except in cases of prostatic enlargement and only for the same reason as it is indicated in prostatic hypertrophy. We feel that Judd's statement is accurate: "Drainage of the bladder even as a preliminary step will seldom help enough to warrant its being done." The bladder is

Fig. 8—Metaplasia of lining cells. The cells are typically squamous in type

filled with sterile water or a mild antiseptic solution, such as mercuric oxycyanide, 1:10,000.

A midline incision of ample length is made down through the bladder as for cystotomy. The peritoneum is reflected upward with the gauze-covered finger as far as necessary for the particular case. In some instances we have found it desirable to do a complete extraperitonealization of the bladder. This has been accomplished in some instances by cutting and doubly ligating the urachus and then bluntly dissecting the peritoneum from the bladder wall. In others it was necessary to follow Voelcker's technic of extraperitonealization.

After the peritoneum has been freed from the bladder by finger dissection, the diverticulum, still filled with water and the bladder still unopened, is freed as far as possible from the perivesical fat and other structures. This part of the operation, we believe is of prime importance, and the ease or difficulty with which it is accomplished depends on the extent and degree of adhesions surrounding the sac. This step is particularly difficult if the sac is thick walled and if there is a marked degree of infection and organized fibrous tissue present. Haste at this time is not advantageous. Cases

in which the entire sac can thus be freed extravasically are those in which the adhesions are few or easily detachable and are suitable for extravasical resection. The bladder is then emptied by the catheter left in place. The mouth of the diverticulum, including a cuff of normal bladder wall, is circumcised and the sac removed in toto. The bladder can then be explored by the finger and if no further operation is contemplated, such as prostatectomy or resection of the vesical neck, the bladder may be closed.

This is done in the usual manner of closure used after prostatectomy, namely, closure by two layers of sutures, care being taken to invert the mucosa. A large drain is left as high as possible in the bladder. Drainage is left to the site of the fundus of the sac that has been removed. This is of great importance and should be adequate. We have found large Penrose tubes or bullet drains satisfactory. The space of Retzius is likewise drained. These drains are left in for at least four days.

Diverticula that are markedly adherent to the surrounding structures and cannot be freed in their entirety require a slightly different method of approach. Most of our cases belong to this class and the technic used was as follows.

All steps are similar to those already described including the freeing of the sac, which in this type of diverticulum cannot be entirely accomplished extravasically. Therefore the bladder is emptied as before and opened between Allis clamps. The orifice of the diverticulum is visualized and stretched with 8-inch forceps so as to admit the index finger of the left hand. Then with the left index finger within the diverticulum and one or two fingers of the right hand outside the bladder, the sac in most cases can be entirely

Fig 9—Squamous cells moderate fibrosis of submucosa and infiltration of lymphocytes endothelial cells and occasional leukocytes

freed. It then may be inverted and resected intravascularly or it may be removed extravasically, as has been described. In certain instances, even with this technic it has not been possible to free the fundus of the sac, either on account of its depth or because of the extreme degree of its adhesions. In these cases we have used a modification of the technic described by Marion and Lowrey and Gutierrez

namely, making an incision to the neck of the sac and also into the sac in its long axis so that the adherent portion is made readily accessible. We have found it necessary to incise the sac in its long axis, so that only from three-fourths to an inch remained unopened, and this small fundus was then separated from the surrounding tissue. Closure of this wound in the bladder is done as has been described and the drainage is the

Fig 10—Incision of bladder wall to neck of diverticulum

same. In one case into which the orifice of the ureter opened, the method described by Hugh Young¹⁰ was followed minutely and effected a complete cure. The details of the technic will not be repeated here.

In cases in which the diverticulum involves the dome of the bladder and when the peritoneum cannot be stripped from the bladder wall or from the diverticulum, it is necessary to open the peritoneum before incising the bladder. Then after making the repair of the peritoneum by uniting the two leaves together, or suturing them low down on the posterior wall of the bladder, the resection of the diverticulum usually proceeds readily, unless the diverticulum is of excessive size.

During the enucleation of a diverticulum the vas deferens or the ureter or both may be exposed and great care must be used to preserve their integrity. Occasionally the sac may be adherent to important blood vessels and may not be detachable without grave risk of injury to them. In such cases it may be necessary to leave the fundus of the diverticulum in situ, this may be done without jeopardizing the success of the operation.

REPORT OF CASES

The following cases are typical of the different varieties encountered in a series of fourteen.

CASE 1—W, a man aged 38 had passed gravel and had been operated on for vesical stone at another hospital. He

complained of burning and difficult urination. This case is rather unusual as the source of the obstructive process was undoubtedly stricture of the urethra, following traumatic rupture of the urethra at the age of 13. Cystoscopic examination showed the opening of a diverticulum above and medial to each ureteral orifice. Some cystitis was present. Both ureteral orifices were normal except for partialing in the general inflammation present and catheters passed readily to each pelvis. Roentgenographic examination—anteroposterior cystograms—did not reveal either diverticulum seen at cystoscopy, but lateral and semilateral cystograms visualized two moderate sized sacs.

CASE 2—M F a man, aged 40 entered the hospital on a litter on account of multiple arthritis of undetermined origin, and under routine examination was referred to the urologic department for study of the genito-urinary tract. Cystoscopic examination revealed a moderate grade of generalized cystitis. The left ureteral orifice was normal and the right ureteral opening was not located, but in the neighborhood was seen an orifice apparently 0.5 cm wide opening into a large diverticulum. Roentgenographic observation showed a large diverticulum on the right side of the bladder. At operation the right ureteral orifice was found in the diverticulum.

CASE 3—H, a man, aged 44, entered the hospital on account of difficulty and burning on urination. He had had sounds passed several years before for strictures in the membranous and penile urethra. Cystoscopy revealed the large orifice of a diverticulum lateral and distal to the right ureteral orifice and into it a considerable length of a shadowgraph ureteral catheter was coiled. There was seen a large vesical stone

Fig 11—Finger of left hand deep within sac. Bimanual enucleation of sac.

present resting on the trigon. Cystograms revealed a large diverticulum of the right side of the bladder. Flat roentgenograms showed the coiled shadowgraph catheter, the large stone in the bladder and the shadow of a similar stone which proved to be in the lowest portion of the ureter.

CASE 4—M C a man, aged 76, entered the hospital on account of difficulty of urination, hematuria and inability to empty the bladder. He had been rising three or more times a night for at least eleven years. Cystoscopic examination revealed the usual observations of a trilobar prostatic enlargement with marked trabeculation. Midway on the right lateral

wall was seen a stone projecting about 2 cm into the bladder. It was touched with a ureteral catheter but could not be dislodged from its position. At operation it was found to be part of an elongated finger-shaped stone practically filling a diverticulum of similar shape.

CONCLUSIONS

1 Increased intracystic pressure due to obstruction or infection or both play an important role in causing

Fig 12—Appearance of bladder wound after excision of diverticulum including zone of normal bladder wall. Beginning closure by interrupted chromic catgut sutures.

herniation of the bladder through a congenitally weak area.

2 Congenital diverticula show no histologic characteristics to differentiate them from the acquired type.

3 There is no diagnostic subjective symptom of bladder diverticula. Dysuria over a long period of years, and the necessity of emptying the bladder twice in a short time, may be considered suggestive symptoms.

4 Cystoscopy and cystography are the two important methods of diagnosis.

5 Complete surgical removal is indicated in all cases in which the general condition warrants operative intervention.

6 Preliminary drainage accomplishes little in preparing a patient for radical resection.

7 The technic described, with necessary modifications, has proved satisfactory in our hands.

The Emotions of Men—The individual who finds life most dull and uninteresting is the one whose every need is provided for. He never enjoys life because he never misses anything he is never given a chance to really want. He is without motive without ambition. And how could it be otherwise? Ambitions are not stirred, aspirations are not kindled, unless there are desires strong but unsatisfied, unless there are objects, alluring but out of reach, objects which beckon and tantalize by receding when we would embrace them.—I and Frederick, H. *Emotions of Men*, New York McGraw-Hill Book Company, Inc. 1930

THE TREATMENT OF EDEMA

EFFECT OF CALCIUM GLUCONATE ON EDEMA
IN CHILDREN *

WILLIAM S O'DONNELL, MD

AND

SAMUEL J LEVIN, MD

DETROIT

Edema is one of the most serious symptoms of nephrosis and of some types of nephritis, cardiac failure and some forms of undernutrition also may be accompanied by edema

The prominent symptoms of nephrosis are edema of the entire body, often pleural and peritoneal effusions, marked albuminuria, normal nonprotein nitrogen, oliguria, a low concentration or a reduction in the blood protein and the absence of hypertension and renal insufficiency. Other types of nephritis that occur with edema, also nephrosis, will usually, if not arrested, follow a chronic course and develop cardiac enlargement, hypertension, an increase in the nonprotein nitrogen of the blood and chronic kidney changes

In children, these diseases are often accompanied by infection beginning in the upper respiratory tract, which often leads to death from septicemia, pneumonia, erysipelas, peritonitis or a combination of these diseases. Death practically always ensues in the edematous stage of the disease as the body's oxidative processes and immunologic properties are defective during the edematous stage. Baehr¹ states that in children with nephrosis the disease is usually superimposed on a chronic pneumococcus infection in the upper respiratory tract and that eventually most of these children die of a pneumococcus infection of ascites, that is, in the edematous stage of the disease

Many methods have been suggested for the relief of edema from the tissues. The edema is often not complete in all the tissues and returns at the onset of any infection or from an exacerbation of a previous infection or from prolonged loss of albumin through the kidney

The substances and methods commonly used in an effort to get rid of excess fluid in the tissues are the purine substances caffeine, theobromine, theophylline and their derivatives, the mercury compounds mild mercurous chloride, merbaphen and mersalyl, the salts calcium chloride, ammonium chloride, magnesium sulphate and ammonium sulphate, urea, parathyroid extract, thyroid therapy and a high protein diet, concentrated dextrose solution given intravenously, forcing fluids, starvation or any combination of these methods, also, paracentesis of cavities, especially the peritoneum, sometimes is followed by a relief of a generalized edema. Following or during the course of an acute infection such as measles or during a septicemia in children with nephrosis, edema has suddenly disappeared

Calcium gluconate can be given intravenously, intramuscularly and subcutaneously. It is a preparation of calcium with gluconic acid and is a product of pure calcium gluconate containing 93 per cent calcium. It is prepared in ampules containing 15½ grains (1 Gm) of calcium gluconate in about 10 cc of water. It is our purpose to call attention to the effect of the administration of calcium gluconate on edema in chil-

dren. In this report we shall give only the details of the cases that are important

REPORT OF CASES

CASE 1—Earl S, aged 4 years entered the hospital May 29, 1930 with a chief complaint of generalized swelling of the body. He had had measles at 1 year whooping cough at 2 years and pneumonia and otitis media at 3 years. The present illness began one week before admission to the hospital with a 'cold' and without a fever. There was some nasal discharge at this time and a slight cough. The 'cold' was accompanied by a swelling of the eyelids, face and ankles which became progressively worse each day until the entire body was swollen, in which condition he appeared at the time of entrance to the hospital. The child's appetite was good up until the time of this sickness. Nothing else of importance appeared in the history.

On admission to the hospital the patient weighed 30 pounds (13.6 Kg). He appeared well nourished, was not acutely ill and was pale with puffiness of the face and eyes, there was distention of the abdomen, edema of the lower extremities and no edema of the upper extremities, slight edema of the chest wall and moderate edema of the scrotum. The head was normal except for edema of the eyelids, the eyes were practically shut from the edema. The pupils and eye muscles were normal. The ear drums were normal and from the nose there was a profuse mucopurulent discharge. The mouth and teeth were in good condition. The pharynx was very red showing swollen inflamed tonsils filling the throat. The lungs were clear throughout. There was some cardiac enlargement but no murmurs, thrills or arrhythmia. The abdomen was distended 4 or 5 inches above the level of the chest. A fluid wave was present and there was fluid in the flanks. The liver and spleen were not palpable.

The specific gravity of the urine was 1.025. It was acid. Albumin was 4 plus, there were a few granular casts, no red blood cells or leukocytes and no sugar.

Examination of the blood showed the red blood cells to be 4,650,000, white blood cells 9,100, hemoglobin 70 per cent, polymorphonuclears 67 per cent, large and small lymphocytes 33 per cent, nonprotein nitrogen 26.5 per cent per hundred cubic centimeters, cholesterol 248 mg, calcium 4.5 mg, phosphorus 2.1 mg. The serum protein estimation of the blood was not done. The Wassermann test of the blood was negative. The tuberculin test was negative.

Röntgen examination of the chest and sinuses revealed a limited development of all the paranasal sinuses and a slight indistinctness in outline of both intrums. The films of the chest showed some cardiac enlargement. The root gland deposit was distinctly in excess of normal and had the appearance of being secondary to a respiratory infection. There was no evidence of parenchymal disease in either the right or left lung field.

A provisional diagnosis was made of beginning nephrosis and chronically infected tonsils. The child was placed on a mixed diet containing 50 Gm of protein. The child remained in bed and the rectal temperature ranged from 99.6 to 100.6 F. June 10 twelve days after admission to the hospital 10 cc of calcium gluconate was given intramuscularly. The weight at this time was 30 pounds 6 ounces (13.8 Kg). Three days following, June 13 the weight was 29 pounds (13.2 Kg) and on July 6 26 pounds 2 ounces (11.8 Kg). No other treatment was given at this time and no more calcium gluconate was given.

A tonsillectomy was done at this time and there was no return of the fluid following the procedure. The edema was cleared from the extremities, face and chest wall. The fluid was cleared from the abdomen and the abdomen was decreased in size. The child was eating well. Albumin was present in the urine but there were no casts, red blood cells or leukocytes. The blood calcium was 9.4 mg per hundred cubic centimeters, the phosphorus 4.2 m% and the cholesterol 280 mg.

CASE 2—Harriet F, aged 17 months entered the hospital June 25 1930 with a chief complaint of marked swelling of the extremities, upper and lower. She had had no previous

From the Metabolism Clinic, Children's Hospital of Michigan.
1. Baehr, George, quoted by Christman, H. A. 'Nephrosis is a Critique'.
J. A. M. A. 93: 23-25 (July 6) 1929.

acute illness. Seven days before admission she had had a "cold" with a nasal discharge accompanied by a swelling of the neck. The mother stated that at this time she had first noticed the marked swelling of the face followed by the swelling of the upper and lower extremities and the protrusion of the abdomen. The child had been fed milk, cereals, vegetables and fruit and was thought to have been normal up to the time of admission to the hospital.

On admission the patient weighed 17 pounds 8 ounces (8 Kg). She appeared poorly nourished, pale and acutely ill, with puffiness of the face and eyes and swollen, edematous

extremities. The head was normal except for the edema of the face. The eyes showed nothing abnormal. The ear drums were normal. There was a cervical adenitis, the size of half a lemon, on the left side of the neck, and the right side showed a pea sized adenitis. There was a small amount of mucopurulent discharge from the nose. There were twelve teeth present. The mucous membranes were able but otherwise normal.

Fig. 1 (case 3)—Extensive pleural effusion at the time of the generalized edema. Aug. 15 1930

There were moderately enlarged tonsils with chronic infection. There was a dullness over the heart extending to the left axillary line, and on the right side the dullness extended 7 cm beyond the right sternal margin. There was a soft blowing murmur at the apex that transmitted to the axilla, there were no thrills or arrhythmia. The abdomen was distended from 3 to 4 inches above the level of the chest. A fluid wave was not demonstrable. The liver was felt three fingerbreadths below the costal margin. The spleen was not palpable.

The specific gravity of the urine was 1020, it was acid, albumin was 1 plus, there was an occasional leukocyte, no casts or red blood cells and no sugar were present.

Examination of the blood showed the red blood cells to be 3,896,000, white blood cells, 15,000, hemoglobin, 60 per cent, polymorphonuclears, 76 per cent, large and small lymphocytes, 24 per cent, nonprotein nitrogen, 41 mg per hundred cubic centimeters of blood, cholesterol, 178 mg. Other blood estimations were not made. The Wassermann and Kahn reactions of the blood were negative. The tuberculin test was negative.

Roentgen examination of the chest and sinuses revealed a limited development of the sinuses but no clouding. Films of the chest showed a cardiac shadow extending to the left lateral chest wall at the level of the fifth and sixth rib anteriorly. There was an extensive root deposit around the course of the bronchi. The lung parenchyma was clear.

The child was placed on the regulation house diet for her age. She was given 10 cc of calcium gluconate intramuscularly, June 30, and on July 22, twenty-seven days after admission, the weight was 13 pounds 3 ounces (6 Kg) a loss of 4 pounds 5 ounces (2 Kg) since admission. The weight had reached this point, July 12, and remained at this level. A blood transfusion was given at this time and the weight remained stationary. The patient was given small doses of digitalis by mouth and was discharged from the hospital at this time. The urine had increased to a 4 plus albumin content at the time of discharge, and the patient's blood count was red blood cells, 5,400,000, and hemoglobin, 90 per cent, showing an improvement in the anemia.

A provisional diagnosis was made of beginning nephrosis, cardiac enlargement and secondary anemia.

CASE 3—Sophie W. aged 10 years entered the hospital, Aug. 9 1930 with a chief complaint of swelling of the feet, abdomen and eyelids and of pain on urination. She became

sick one month before, at which time she felt listless and weak. There was swelling at this time, she was seen by a physician, who said she had kidney trouble and advised her to go to a hospital. An accurate history could not be obtained on account of language difficulty.

On admission the patient weighed 81 pounds 4 ounces (36.8 Kg). She appeared very edematous, with markedly swollen feet and legs and marked enlargement of the abdomen. The eyelids were red and puffy. The patient also had edema of the upper extremities. The skin pitted readily on pressure over the entire body. The glands were normal in size. The head was normal except for the edema. The eyes were normal. The ear drums appeared normal. There was no discharge from the nose. The teeth were in good condition. The mucous membranes were pale. The tonsils were large and septic. There was a marked swelling of the soft tissues of the neck. The chest was asymmetrical, the left chest was practically immobile. The fremitus was decreased over the entire left chest and was flat to percussion throughout. The breath sounds were absent as was the spoken voice. On the right chest, percussion anteriorly was hyperresonant and the breath sounds were heard throughout. The left border of the chest could not be percussed because of the dullness of the entire left chest. The heart sounds were of good quality. There were no murmurs, thrills or arrhythmia. The abdomen was swollen and tense. There was a shifting dullness present. The extremities showed a marked edema.

The specific gravity of the urine was 1030, it was acid, albumin was 4 plus, a few red blood cells and an occasional hyaline cast were found, there were no leukocytes and no sugar.

Examination of the blood showed the red blood cells to be 3,850,000, white blood cells, 20,000, polymorphonuclears, 80 per cent, large and small lymphocytes, 20 per cent, the non protein nitrogen, 22 mg per hundred cubic centimeters of blood, calcium, 10 mg, phosphorus, 4 mg, and cholesterol 248 mg, other blood estimations were not done. The blood Wassermann reaction was negative.

Roentgen examination of the chest showed a mass of pleural exudate on the left side of the chest, with a resulting displacement of the heart and the mediastinal contents toward the right. The cardiac shadow was partially obscured. There was no evidence in the right thorax and no frank parenchymal disease. The films of the sinuses showed slight cloudiness, but there was no evidence of an exudate in the sinuses.

The child was placed on a regulation house diet for her age and, over a period from August 15 to September 8, was given 155 cc of calcium gluconate intramuscularly and subcutaneously. September 20, she showed a weight loss of 29 pounds 12 ounces (13.5 Kg). There was entire absorption of the pleural exudate and the ascites and abdominal enlargement had entirely disappeared.

Fig. 2 (case 3)—Entire absorption of the pleural effusion after calcium gluconate therapy. No other treatment was used. Roentgenogram was taken Sept. 8 1930.

The patient's general condition was good and she had a much stimulated appetite. The urine examination at this time showed a specific gravity of 1025, acidity, albumin 1 plus, no sugar, red blood cells or leukocytes were found and only an occasional granular cast. The blood cholesterol was 263 mg per hundred cubic centimeters, the nonprotein nitrogen 32 mg, calcium, 9.9 mg, and phosphorus, 3.3 mg per hundred cubic centimeters.

A provisional diagnosis was made of beginning nephrosis, pleural effusion, ascites and generalized edema.

The roentgen examination of the chest, September 19, showed that there had been a complete absorption of the fluid in the thorax. The root markings were prominent and the heart shadow was normal in size.

COMMENT

The administration of the calcium gluconate was not accompanied by any undesirable symptoms. There was no nausea nor vomiting. The calcium gluconate did not seem to have any harmful effects on the edematous tissues into which it was given. If the calcium gluconate is given in small doses, 10 cc over different areas subcutaneously, the effect is less painful. Any amount of fluid given intramuscularly, sufficient to cause pressure in the muscle tissue, may cause pain and swelling of the tissue. There was complete disappearance of the hydrothorax, as evidenced by repeated roentgen examinations and clinical signs. The ascites disappeared and there was a decrease in the size of the abdomen. There was no unfavorable change in the urinary condition during or following the administration of the calcium gluconate that would lead us to believe that the calcium gluconate had any harmful effect on the kidneys. The calcium salt dehydrates the kidneys, which also may be edematous.

Results of Treatment

Case	Date	Weight	Treatment	Weight Loss
1	6/10/30	30 lbs 6 oz	10 cc calcium gluconate	
	6/13/30	29 lbs		1 lb 6 oz
	7/ 6/30	26 lbs 2 oz		4 lbs 4 oz
2	6/30/30	17 lbs 8 oz	10 cc calcium gluconate	
	7/10/30	14 lbs		
	7/22/30	13 lbs 3 oz		4 lbs 5 oz
3	8/15/30	81 lbs 4 oz	10 cc Ca G	
	8/18/30		10 cc Ca G	
	8/20/30	79 lbs	20 cc Ca G	2 lbs 4 oz
	8/23/30	78 lbs 8 oz	20 cc Ca G	2 lbs 12 oz
	8/24/30	77 lbs	20 cc Ca G	4 lbs 4 oz
	8/28/30	75 lbs 4 oz	30 cc Ca G	6 lbs 4 oz
	8/30/30	68 lbs 4 oz	15 cc Ca G	13 lbs
	9/ 3/30	65 lbs	20 cc Ca G	13 lbs 4 oz
	9/ 8/30	63 lbs	10 cc Ca G	18 lbs 4 oz
	9/13/30	57 lbs 4 oz		24 lbs
	9/20/30	51 lbs 8 oz		29 lbs 12 oz

A general improvement in the appetite and general condition of the children was noticeable after they were free from edema, also, the dehydration of the mucous membranes of the respiratory tract seemed to have a good effect on the patient's resistance to the respiratory infections which were the onset of the usually fatal infections that complicate nephrosis in children in the edematous stages of the disease. In cases 1 and 3 there was a drop in the cholesterol of the blood after the edema disappeared. In case 1 there was a marked change in the calcium of the blood from 4.5 to 9.3 mg per hundred cubic centimeters of blood following treatment. The calcium has remained at a normal level since this time.

The weight loss in the three cases was, respectively 4 pounds 4 ounces (2 Kg) 4 pounds 5 ounces (2 Kg) and 29 pounds 12 ounces (13.5 Kg) which depended on the size of the child and the stage of edema to which it was allowed to progress. There was no evidence of an alkalosis, such as depressed or irregular respirations, cyanosis, tetany or convulsions. As the calcium gluconate is slightly basic we thought that the calcium gluconate may possibly affect the sodium bicarbonate level of the blood. That no symptoms occurred is

important. To patient 3 we gave 155 cc (240.55 grams) of calcium gluconate intramuscularly and subcutaneously in the buttocks and under the scapulae, over a period of twenty-one days, and the weight loss of edema followed to its lowest level—a 29 pound loss in thirty-six days. At this rate it took about 5.3 cc, or 7½ grams per pound of water, in reducing the patient. We believe that the amount of edema could be calculated from the patient's weight and height, and then the amount of calcium gluconate necessary could be given in one or two doses to reduce the edema quickly. This might become necessary in the face of an impending serious infection. We have not had enough cases at present to prove how soon we could free the patient of the edema without any harmful effects, also to check up the dosage accurately.

Nephrosis has often been referred to as protein diabetes by Epstein,² Kollert,³ Lowenthal⁴ and others on account of the loss of albumin through the kidneys and on account of the low blood protein. In the days before insulin children with diabetes developed acidosis, and with the accompanying infections, which started mildly and progressed seriously the outcome was soon fatal. Anything that can keep the patient from developing edema or that can relieve the edema quickly is good therapy. We should be able to prevent the return of the edema at its onset, at the beginning of an acute infection, with the use of calcium gluconate in small doses and keep the edema from developing to a serious degree until the blood protein is replaced by sufficient protein feeding, continued over a sufficient length of time. We have been able to accomplish this at the onset of a slight respiratory infection in two of the cases that returned with beginning edema of the face last fall.

Munk,⁵ Volhard,⁶ Fahr,⁷ Epstein,² and others have emphasized the importance of the protein loss in these cases and the need of giving sufficient protein in the diet to minimize the protein loss by the kidney as well as from the blood, and the importance of not giving too much protein so that kidney damage will be accentuated. It is necessary to keep these patients on a sufficient, measured amount of protein to promote further good treatment in order to restore the lost blood protein and to keep the kidneys from secreting too much albumin. Cowie, Jarvis, Cooperstock and Nakao⁸ have shown in a study of nephrosis in a child that from 1 to 3.75 Gm of protein per pound of body weight is sufficient to restore the blood protein level and to decrease the protein loss from the kidneys.

The use of calcium gluconate and the optimal protein diet should prove useful in the successful treatment of children with nephrosis. Up to the present the mortality of children with nephrosis accompanied by infections has been 50 per cent or higher.

ENORMOUS INCREASE OF HEART VOLUME WITH MITRAL STENOSIS

REPORT OF A CASE

EDWARD F. BLAND, M.D.

Dalton Fellow Cardiac Clinics and Laboratory Massachusetts General Hospital

GERARDO M. BALBONI, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

The association of auricular dilatation with mitral stenosis was well appreciated by clinicians a century ago.¹ It has long been recognized that in the presence of definite obstruction to the free flow of blood through the mitral orifice the first of the cardiac chambers to be noticeably affected by the altered relations of intra-cardiac pressure is the left auricle, which increases in size, largely the result of dilatation. This enlargement is often accompanied by an actual hypertrophy of the muscle fibers and an increase in the thickness of the auricular wall. Later the right ventricle and right auricle may be affected in a similar manner. More recently, the profound effect that mitral regurgitation alone, in the absence of stenosis, may at times exert in a similar direction has attracted considerable attention and is well shown in the unusual case recorded by Adam² of a traumatic perforation of the anterior cusp of the mitral valve resulting from a revolver shot wound. Pure mitral regurgitation developed and at postmortem examination six years later all four chambers of the heart were found to be greatly hypertrophied and dilated. Although adhesive pericarditis followed the removal of blood from the pericardium at the time of the injury, the adhesions were not massive and it seems likely that the mitral regurgitation in this instance was the factor primarily responsible for the extensive cardiac changes. Bach and Keith,³ in a recent report, called attention to a case of extreme dilatation of the left auricle as a complication of rheumatic mitral regurgitation, with fused cusps but no stenosis, the orifice admitting three fingers easily. We have recently reviewed at the Massachusetts General Hospital the postmortem observations of twenty-six cases presenting an unusual amount of left auricular dilatation. Changes in the mitral valve, the result of a previous rheumatic infection, were present in every case. In 62 per cent of the cases the circumference of the mitral valve measured 7.5 cm. or less, that is, anatomic mitral stenosis was present, while in 38 per cent of the cases the mitral orifice exceeded 7.5 cm. in circumference and mitral regurgitation was the predominant feature. Auricular fibrillation is a well recognized additional factor predisposing to passive dilatation of the auricles and has usually been found present in those cases in which the enlargement is extreme, it was present in eighteen (69 per cent) of our series of twenty-six cases of auricular enlargement at the Massachusetts General Hospital.

The extraordinary extent to which the auricles may dilate while the heart continues to function with a fair degree of efficiency is of considerable interest both clin-

ically and pathologically. The position of the auricles and their close proximity to important adjacent structures in the mediastinum is such that even moderate enlargement may be responsible for profound functional alterations in other organs the result of pressure on nerves, blood vessels or bronchi. At other times extreme dilatation, as in the case we are reporting, may be accompanied by relatively insignificant disturbances either in the heart or elsewhere in the body. King⁴ in 1838, was the first to call attention to the possibility of a partial collapse of the left main bronchus by an enlarged left auricle. More recently Stoerk⁵ has made a comprehensive study of the anatomic relations of the mediastinal contents and has pointed out the close relation of the left main bronchus and the upper surface of the left auricle, while the roentgenologic demonstration of left auricular enlargement has been recently studied by Steele and others.⁶

We are reporting herewith our observations on a patient with enormous increase of heart volume asso-

Fig 1—Orthodiagram taken four months before death showing the enormous size of the cardiac shadow

ciated with disease of the mitral valve giving rise to both stenosis and regurgitation, this case presented several features of considerable interest

REPORT OF CASE

M. D., a man, aged 28 an Italian, had been under our observation for nineteen years. He was seen by one of us (G. M. B.) for the first time in March 1911, at the age of 9 years with an attack of acute rheumatic fever. There was evidence of cardiac disease at this time, and a loud blowing systolic murmur was audible over the precordium best heard at the apex. He spent eleven weeks in bed with this attack.

In 1912, a year later, he was again seen because of dyspnea on exertion. Well marked mitral stenosis and regurgitation were present. He felt considerably better after two weeks of rest in bed. In 1915 there was a second attack of acute rheumatic fever and the following year (1916) he entered the Massachusetts General Hospital for tonsillectomy. His heart was found to be moderately enlarged with a rather rapid

rate and normal rhythm. The sounds were of fair quality, with a snapping first sound at the apex and a marked accentuation of the pulmonary second sound. The characteristic murmurs of mitral stenosis and regurgitation were present. The tonsils were removed and he was discharged two days later.

In 1917 he visited the outpatient department for a follow-up examination, having been in good health since his hospital entry and essentially without symptoms except for moderate dyspnea on exertion. At this time his pulse was noted to be slightly irregular (auricular fibrillation?) at a rate of 108 per minute. Roentgen examination showed the heart to be enlarged, of a "mitral" shape with extreme enlargement of the auricles, especially of the left, the total transverse diameter of the heart being 13 cm, and the transverse diameter at the base measuring 11.5 cm. In 1920 there occurred an attack of slight congestive failure accompanied by dyspnea, cyanosis, weakness and palpitation. Auricular fibrillation was noted definitely at this time. Digitalis therapy was started, resulting in considerable improvement in the patient's condition and he was able to lead a fairly active life, though at times it was necessary for him to spend one or two months in bed because of weakness and dyspnea on exertion.

In January, 1928, at the age of 26 years, he entered the hospital for a second time because of frequent headaches associated with a feeling of extreme exhaustion at the end of the day, increasing dyspnea on slight exertion, and a progressive loss of weight during the preceding three months. In spite of these symptoms, however, he had continued at work, taking digitalis intermittently and inadequately.

The patient was well developed and well nourished. On examination he lay flat in bed in no distress. Cyanosis was

scapular region to the base. Over the apex of the left lung there was an increase in the intensity of the breath sounds. The heart was markedly enlarged to the right and to the left, with a diffuse heaving impulse visible over the entire precordium but of maximum intensity in the sixth intercostal space in the anterior axillary line 10 cm to the left of the midsternal line. The left border of dullness at this point was 11 cm, being 2.5 cm outside the midclavicular line. The right border of

Fig 3—Front view of the heart in the present case with similar view of a heart of normal size (weight about 325 Gm). Note the enlargement of the right auricle and ventricle and the enormous increase in size of the left auricle. A small amount of lung tissue is shown adherent to the top of the left auricle. Cannulas and tubes are shown in the superior vena cava and one of the pulmonary veins introducing fluid to keep the heart filled. The pencil at the apex of the heart points to the interventricular sulcus.

Fig 2—Appearance of heart within the pericardium occupying almost the entire width of the thorax. Only the upper lobes of the lungs are visible. Below the diaphragm is to be seen the enlarged congested liver. We are indebted to Mr. Philip A. Nutting for the photographs in this case.

not present but there was a slight icteric tinge to the sclerae. The superficial veins of the arms and thorax were somewhat dilated and there was well marked pulsation of the jugular veins in the neck. The chest was clear but posteriorly there was evidence of abnormality at the base of the left lung with dullness on percussion, distant breath sounds, diminished tactile fremitus and whispered voice extending from the mid-

dullness in the fifth interspace measured 8 cm from the midsternal line. At the apex, well marked systolic and diastolic thrills were palpable. The rhythm was absolutely irregular and the rate was from 60 to 65 per minute. The sounds at the apex were almost obscured by loud blowing systolic and rumbling middiastolic murmurs. Over the aortic area and along the left sternal border there were less intense blowing systolic and early moderately high pitched diastolic murmurs. No first or second sound could be heard in the tricuspid area. The radial pulse was of small volume. The blood pressure was 120 mm of mercury systolic and 80 mm diastolic. The abdomen was somewhat tender and resistant in the epigastrium and right upper quadrant with a moderate increase in liver dullness but the edge could not be felt. There was a well marked systolic pulsation in this region. Clubbing of the fingers and edema of the extremities were not present, and the remainder of the examination was normal.

The laboratory data were essentially normal. Repeated urine examinations showed no abnormalities. The phenolsulphonphthalein test of renal function showed a 50 per cent excretion of the dye in two hours. Examination of the blood revealed a red cell count of 5,800,000 on two occasions and a hemoglobin determination of 80 per cent; the smeared specimen showed nothing remarkable. A culture of the blood showed no growth. The Wassermann reaction on the blood serum was negative; the icteric index was 12 and the nonprotein nitrogen 35 mg per hundred cubic centimeters of blood. An electrocardiogram showed auricular fibrillation with a ventricular rate of from 50 to 60 and low T waves without abnormal axis deviation.

Roentgen examination of the chest revealed marked dullness obliterating the outline of the border of the heart and diaphragm on the left side with the upper border somewhat curved sharply defined and opposite the third rib anteriorly. The heart shadow extended to the right farther than normal. The shape was not that usually seen with free pericardial fluid but was thought to be due to tremendous enlargement of the heart or to encapsulated fluid.

The patient remained in the hospital for two weeks during which time there was considerable symptomatic improvement and at the end of this time he was discharged home with the

diagnosis of chronic rheumatic heart disease, mitral stenosis and regurgitation, probable aortic and tricuspid insufficiency, possible adhesive pericarditis and auricular fibrillation. After discharge from the hospital he continued with a daily maintenance dose of digitalis and except for two transient attacks of severe "prostration" and collapse he was able to lead a relatively active life frequently driving an automobile 40 miles a day. Easy fatigability and dyspnea on exertion were his only symptoms. Roentgen and orthodiagraphic examination of the chest in February, 1930, showed a tremendous heart, but

foramen ovale was closed, and the coronary sinus was normal and protected by a valve. The auricular appendages except for their unusual size, were not remarkable and there was no evidence of an antemortem clot. The coronary arteries were patent. The wall of the left ventricle measured 13 mm. in thickness, the right ventricle 4 mm., the right auricle from 15 to 15 mm., and the left auricle 1 mm.

The pleural cavities contained no free fluid but were markedly diminished in size by the encroachment of the enlarged heart. Considerable anteroposterior flattening of the trachea from pressure of the distended left auricle was present, and the angle formed by the primary bronchi was markedly widened. Considerable anteroposterior flattening of the left main bronchus was present also (fig 5). The lungs were greatly diminished in size by compression of the enlarged heart being estimated at one-third to one-half that of their expected size. The left lower lobe was completely collapsed, while the remaining lobes showed compression and congestion of moderate degree.

The liver was much enlarged, weighed 1,600 Gm., and was displaced downward. The normal lobulation was replaced by small irregular masses of slightly bulging, yellowish brown tissue. There was slight congestion of the kidneys, otherwise the remaining organs were essentially normal. An examination of the brain was not permitted.

Microscopic examination showed the muscle fibers of both ventricles of the heart to be markedly elongated and narrowed. The auricular walls were extremely thin and consisted almost solely of connective tissue with very rare muscle fibers. There was no evidence of myocarditis. Section of the lung showed congestion with the alveoli partially filled with a delicate exudate composed of albuminous detritus, a few red blood cells and mononuclear cells. There were present also collections of hemosiderin filled alveolar phagocytes (heart failure cells). The liver showed a moderate amount of congestion, the hepatic cells being decreased in number and replaced by areas of congestion, necrosis and fibrosis. There were several large areas of fibrosis scattered throughout the organ, chiefly in the periportal regions. The kidneys showed considerable postmortem degeneration, so that the finer histologic changes of the glomeruli and tubules could not be made out with certainty. Scattered sclerosed glomeruli, patches of

Fig 4—Left lateral (A) and right lateral (B) views of the heart in the present case. Note the muscle bands in the right auricular wall and the posterior protrusion of the enormous left auricle.

essentially the same in appearance as two years previously (fig 1). In June, 1930, the patient went swimming, drove home and shortly afterward, while dressing, suddenly fell forward and died immediately.

Postmortem examination, performed seventeen hours after death, showed no abnormality of the surface of the body. When the thorax was opened the heart was found to occupy almost the entire expanse of the thoracic cage, only a small part of the upper and lateral portions of each pleural cavity being occupied by the lung (fig 2). The left margin of the heart was in contact with the left thoracic wall, the right margin extended to within 1 cm. of the right thoracic wall, so that the heart occupied almost the entire transverse diameter of the thorax. The transverse diameter of the heart in situ was 215 cm., which corresponded closely to the transverse diameter of the shadow in the orthodiagram made four months before death, the internal diameter of the thorax, post mortem, was 225 cm. The pericardium was slightly thickened and adherent to the surface of the left auricle over an irregular area of moderate size on the lateral and anterior surface of the latter. Otherwise it showed a normally close investment of the heart with glistening surfaces. The heart, after being removed from the thorax and filled with fixing solution (Klotz 1) with the main vessels ligated, displaced the enormous volume of 4,600 cc. of water (figs 3 and 4, the displacement of the normal heart is from 700 to 800 cc.). After removal of the pericardium and all attached structures (except a small section of the trachea and primary bronchi) together with all clot from the interior, the heart weighed 850 Gm. The capacity of the left auricle was great, amounting to 1,760 cc. The right auricle was considerably dilated also and held 660 cc., the right ventricle held 320 cc., and the left ventricle 70 cc. When the heart was opened, the mitral valve was found to be diseased, 'fish mouth' in character with considerable thickening of the valve leaflets but with a circumference of the irregular orifice of 85 cm. (dimensions of the opening measuring 15 by 3 cm.). The aortic valve showed evidence of slight thickening and stenosis the orifice measuring 55 cm. in circumference. Considerable dilatation of the tricuspid ring was present but no definite evidence of valvular disease the circumference was 145 cm. The pulmonic valve was not remarkable and showed no evidence of structural change (circumference 8 cm.). The

Fig 5—View of the heart from above and behind showing the bifurcation of the trachea (T) with the left bronchus (L.B.) displaced upward and flattened by pressure from an enormous left auricle.

lymphocytic infiltration, tubular atrophy, and fibrosis suggested healing and healed infarcts. The results of the examination of the spleen, pancreas, suprarenal glands and aorta were essentially negative. The anatomic diagnosis was chronic rheumatic heart disease, well marked chronic mitral endocarditis, slight chronic aortic endocarditis, dilatation of the tricuspid valve, hypertrophy and extreme dilatation of the heart, chronic passive congestion, cardiac cirrhosis of the liver, and healed infarcts of the kidney. The cause of sudden death was not determined.

COMMENT

The extraordinary displacement of the heart (4 600 cc) is the outstanding feature of this case. The literature which is notably deficient in reports of heart volume (displacement), contains no record that we have found of an actual measurement equalling that in the present case. The volume of the muscle mass of normal hearts has been comprehensively studied by Beneke⁷ in a large series of cases of both males and females of all ages up to 80 years. The volume of the normal

Dimensions of the Filled Heart After Removal from the Thorax

	Cm
Greatest circumference of the auricles	65.5
Widest diameter across the auricles	24.0
Greatest anteroposterior diameter (left auricle)	17.0
Circumference of left auricle	46.0
Vertical diameter of left auricle	12.5
Circumference of right auricle	44.0
Anteroposterior diameter of right auricle	15.5
Vertical diameter of right auricle	14.0
Greatest width of ventricles	16.5
Greatest depth of ventricles	8.0
Base of aorta to apex	18.0
Superior vena cava to apex	17.0
Circumference of aorta	7.0
Circumference of pulmonary artery above valve	6.5
Circumference of inferior vena cava	10.5

adult male heart muscle was found to vary from 260 to 290 cc, approaching the latter figure with advancing years. The muscle volume of women's hearts averaged slightly less than that of the men in the same decade of life. Hochrein⁸ has determined the capacity of the various cardiac chambers in thirty normal hearts, and the total capacity of the four chambers averaged 561 cc. On the basis of these investigations it appears that the normal displacement of the filled heart should be approximately 800 cc, varying somewhat according to the age and the sex of the patient. It is of interest that a normal heart weighing 325 Gm which we recently filled with fluid after the main vessels were ligated actually displaced 700 cc of water, a figure that is in a relatively close proximity to the expected volume (displacement) estimated by combining the average values for capacity and volume given by Hochrein and Beneke. In the case of the greatly enlarged heart here recorded, cardiac hypertrophy was far less a factor than dilatation in causing the extreme enlargement, the weight was 850 Gm, which, although considerable, has often been exceeded, Smith⁹ has recorded a heart that weighed as much as 1 755 Gm.

The capacity of the auricles was remarkable also. The left auricular capacity (1,760 cc) has been exceeded by only three cases previously recorded, namely that of Minkowski¹⁰ in which the left auricle held 3 liters, Muller's¹¹ case with a left auricular capacity of 2.5 liters, and Goedel's¹² with a left auricular capacity of 2 liters. The right auricular capacity of 650 cc appears to be a record one, we have found none larger reported.

It is of considerable interest that in spite of the unusual size of the heart in our patient he was able to lead a relatively active life up to the time of his sudden death, the cause of which is obscure. Although

the brain was not examined, it seems unlikely that a cerebral embolus was responsible for his sudden exit, a more likely explanation being some unusual disturbance of cardiac mechanism, such as ventricular fibrillation or standstill.

SUMMARY

1 A young man with mitral disease, under observation for nineteen years, lived a relatively active life up to the time of his sudden death, in spite of an extraordinary amount of cardiac enlargement and an extreme degree of auricular dilatation.

2 The volume (displacement) of the filled heart was 4,600 cc, which is from six to seven times that of a normal sized heart and establishes a record for future comparison. The literature is notably deficient in measurements of heart volume (displacement), a determination that should be a helpful indication of the degree of responsibility of cardiac dilatation in the production of cardiac enlargement. In the case recorded cardiac hypertrophy was far less a factor than dilatation in causing the extreme enlargement; the weight was 850 Gm, which has often been exceeded.

3 The left auricle had a capacity of 1,760 cc, a measurement exceeded by only three other cases in the literature. The right auricle held 650 cc, which appears to be a record capacity.

VESICO-INTESTINAL FISTULAS *

J. H. MORRISSEY, M.D.

NEW YORK

In a communication¹ read before the Section on Urology of the American Medical Association in 1927, the possible extension of inflammatory processes in viscera adjacent to the superior pelvoretal space was clearly emphasized. Instances were cited in which infection originating in the seminal vesicles, superior urethra and other structures had spread to this space and, forming inflammatory deposits, had subsequently involved other juxtaposed organs. It was in this communication that pertinent data relative to the etiology of vesico-intestinal fistula were brought to light.

The literature on the subject records a proportionately limited number of cases. Prior to 1870, when Blanquinque's² article appeared there are a few isolated references in mainly of French source, by Boyer,³ DeSault³ and Chopart.³ In the seventeenth century Schenckius,³ a German practitioner of Freiburg, noted the occurrence of a vesico-intestinal fistula in a fellow practitioner consequent on degenerative changes in a neoplasm of the sigmoid. In the same century, the Italians Cardano and Benvenuti⁴ independently reported similar cases. While the ancients did not fall short of noting at least one instance since the second century, the Ephesian physician Rufus⁴ quoted a certain Praxagoras as having seen a case of vesico-intestinal fistula—probably the famous Praxagoras of Cos the teacher of the greatest anatomist of the Ancients, Hierophilus.

The modern phase of this work began with the epochal contribution of Harrison Cripps⁵ on "The

⁵ Cripps, Harrison, *The Passage of Air and Faecal Matter with the Urine*. London 1868.

Passage of Air and Faecal Matter with the Urine" Written in 1885, many of the fundamental facts and views set forth therein still remain unchanged. He collected sixty-three cases and concluded that over 70 per cent of these were consequent on some inflammatory mischief, including ulceration. In fifteen instances absolute evidence was obtained that the fistulas were the result of an abscess bursting both into the bladder and into the bowel. Some of these appeared to have followed confinement, some stricture of the rectum. In a consideration of cancer of the rectum and its frequency, he concluded that, although there was considerable destruction of tissue, numerous fungoid granulations were produced which had a tendency to block contiguous cavities, and even in instances in which cancer had been the primary or contributory cause, the actual perforation of the bladder seemed to have resulted just as often from the bursting of the secondary abscess as from the direct extension of the growth itself.

In 1899 Pascal⁶ reviewed the subject matter comprehensively from all angles, quoting the work of Dumenil³ (1884), who proposed colostomy as a method of treatment, the work of Le Dentu⁷ (1884) and his transvesicular approach, which was repeated by Pousson in 1895, the views of Czerny⁸ (1887), who advocated a laparotomy, and the contributions of Tuffier³ and Dumont,³ who described appendicovesical fistulas.

Within recent years this entity has attracted the attention of a number of eminent American and English urologists and surgeons. Parham,⁷ in 1895, attempted to close a fistula by opening the bladder and by suturing the fistulous opening. He failed. In 1911 Chute⁹ reported two cases that came under his care, in both of which operation was attended with unsatisfactory results. In an analysis of the causes he felt that the fistulas arose from increased pressure in the bowel due to constipation and that fatty infiltration of the bowel wall was a predisposing factor in their development. Similarly, individual cases were reported by Keefe,¹⁰ McKenna,¹⁰ Rankin, Lauterman,¹¹ Judd and others. Lately this entire subject has been linked with diverticulitis and the literature pertaining to it has consisted primarily of case reports dealing particularly with the rupture of a sigmoidal diverticulum into the bladder. This view has received the sanction of Bryan.¹² He claimed that the most common site of the diverticula was in the neighborhood of the sigmoid flexure and since the distal end was more frequently the location, its adjacency to the bladder rendered rupture most likely. In the forty-two case reports that he collected, twenty-nine patients were males and thirteen females, the average age was between 50 and 60, he concluded that over 50 per cent were due to diverticulitis.

Of interest is Craig and Lee-Brown's¹³ analysis of the 195 cases reported by Pascal. These authors noted

a fistulous tract distributed as follows: 113 from bladder to rectum, 42 from bladder to colon, 26 from bladder to cecum, 6 from bladder to sigmoid, 7 from bladder to appendix. In 1915 Cunningham¹⁴ reported a total figure of 342 cases of vesico-intestinal fistula, basing the totality on 286 cases culled by Pascal up to 1900, 42 by Pristavescio¹⁵ from that date to 1912, and his own additional 8 up to the time of the publication of his articles.

Etiologically it must be said that these fistulas are secondary to some causative factor, and not infrequently the result of malignant growths, pelvic tuberculosis, syphilis and rarely actionary cases. These have been referred to as spontaneous fistulas by Oraison. A case of tuberculosis of the seminal vesicle has been reported in which an abscess perforated into both the rectum and the bladder. A much more common origin is an inflammatory focus, productive of rectal ulcerations, perirectal abscesses, diverticulitis and appendiceal abscesses. The French authors mention adnexal inflammatory masses in women as a potential cause, and likewise destructive diseases of the pelvic bony structure. These, of course, are exceedingly rare, although rupture of a tubo-ovarian inflammatory mass into either the rectum or the bladder independently have been reported by gynecologists. It must be borne in mind that oftentimes both the superior and the inferior pelvic rectal spaces may harbor a smoldering focus of infection—organisms originating in adjacent inflamed areas—which may under favorable circumstances flare up. Doubtless the increased incidence of inflammatory diverticulitis as a productive factor is due, in the main, to a better investigation of these cases, including roentgenographic study. This diagnostic adjuvant Cripps did not possess and consequently he failed to note diverticulitis in the fairly large number of cases he had occasion to investigate and report. Cripps does mention, however, two cases in which stone in the bladder was undoubtedly the cause of a vesico-intestinal fistulous development. Since the war, a number of fistulas have been reported the direct result of external violence, usually consequent on gunshot wounds, shrapnel fire, stab injuries and actual fracture of the pelvic bone with fragmentation. To this category there may be added surgical trauma, resulting from intestinal injury in debilitated subjects, extirpation of pelvic tumors, and the now discarded method of puncturing the bladder by way of the rectum.

The lesions resulting in fistulas are less often in the bladder and when located there are usually the result of a malignant growth, vesical tuberculosis or trauma. The location of the opening in the intestinal canal is most common in the rectum, nearly half of the collected cases being in this structure. The next most common location is the sigmoid and next in frequency are the small intestine and the cecum. The location of the opening in the bladder is most frequently situated in the region of the trigon, yet in many cases it has been observed in the posterior wall and a few have been observed on the summit of the bladder. Naturally a case in which the element of infection plays an important part will show a perforation in the region of the trigon, this portion of the bladder being the most fixed whereas the remainder of the viscus will have a tendency to be displaced by a collection of pus. The fistulous

tract between the bladder and the intestinal canal may be a direct communication or a long and tortuous sinus. When the former type, it is generally the result of carcinoma or tuberculosis originating in either the bladder or the rectum, in the latter, it is more frequently the result of an abscess originating between the bladder and the rectum and opening into these regions by apertures situated at different levels.

SYMPTOMATOLOGY

Prior to the establishment of a communication between the bladder and the gastro-intestinal tract, the symptoms are somewhat variable depending on the nature and severity of the disease and on the structure involved. Once a perforation has occurred the symptoms are aggravated and pathognomonic—frequent painful micturitions, the passage of pus, fecal matter and gas via the urethra. If the fecal material is in hard lumps, further difficulties of urination may occur with tenesmus. Feces, however, are not always present in the bladder, the communicating lumen may be so small as to permit solely the passage of gas. But the symptom most distressing to the patient is the uncontrollable escape of flatus, which may occur involuntarily or during the act of straining. The symptoms dependent on the pressure of urine in the rectum are those of proctitis and are seldom of consequence. Later, secondary symptoms occur and, if the suppurative process in the bladder continues, kidney infection with its chain of manifestations takes place and death may ensue.

The prognosis depends on the nature of the primary lesion to which the fistula is secondary. It is naturally most unfavorable in cases in which carcinoma or tuberculosis is the primary cause. In instances in which the communication is due to an inflammatory or traumatic factor, the prognosis is far more favorable.

Treatment is best considered as operative with the radical and palliative phase and nonoperative forms. It must of necessity depend on the nature of the etiologic factor producing the fistulas. When the primary cause is a traumatism or an inflammatory process, such as simple ulceration, abscess or rectal stricture, operative measures offer considerable, but when the intestinal vesical communication is due to carcinoma or a tuberculous process originating either in the bladder or in the alimentary canal, operative measures are seldom successful. In instances in which the fistula appears to have followed the rupture of an intestinal abscess or is due to tuberculous ulceration or to syphilis spontaneous healing under appropriate nonoperative treatment has been known to take place.

Operative Methods—1 Abdominal section and separation of the intestines from the bladder at the point of union and repair of the opening in both organs, or, if necessary, a resection of the bladder and intestine so as to include the tract of the fistula, and the repair of the incision by the method most appropriate in the individual case. 2 Perineal operation through the vagina or perineal surface in cases in which the communication has been demonstrated to be low down in the rectum. Operations conducted from this region have seldom permitted of closing the rectal and vesical opening, but if separation of the adherent intestine from the bladder is accomplished the wound packed, the bladder drained by a retained catheter, the rectum pricked above the rectal opening and the bowels prevented from moving by a liquid diet and liberal use of opiates, success has often been obtained. 3 Colostomy, with the object in view of diverting the flow of feces from

the bladder. This is the ideal procedure. The important point to be determined before performing a colostomy is the location of the intestinal opening, for if the communication is in the small intestine or cecum, colostomy would be without value. 4 Suprapubic cystotomy, with the end in view of allowing free drainage for the fecal contents of the bladder. This palliative measure often resorted to, should be reserved for cases of extensive carcinoma when little else can be done.

Several other considerations as to the etiology of these fistulas must be borne in mind in respect to radium therapy. Several cases of extensive ulceration in the posterior bladder wall following irradiation for carcinoma of the bladder and prostate have been noted. Two cases of slough of the bladder wall were observed¹⁶ with a large fistula. Both patients died.

In another case¹⁶ a fistula developed following irradiation with gold seeds for extensive carcinoma of the uterus. Irradiation of the lateral fornices was too great and the slough eventually resulted in a communication between the intestine and the bladder. Naturally these cases are not reported widespread. It is my opinion that an activating cause in certain cases wherever diverticulitis may exist lies in the presence of postprostatic infection. This focus may have been smoldering for years, contingent on infection in the bladder, and an increased bladder activity set up an inflammatory process which eventually established a fistula of the type described. Two personal cases are recorded in which the passage of gas through the urethra was not noted until after the removal of the prostate.

REPORT OF CASES

CASE 1—A P, seen in January 1925 complained of a sense of pressure in the bladder and of smarting on beginning to void. The discomfort abated and disappeared under bladder irrigations and guaiacol. The discomfort returned three months later and this time responded less satisfactorily to treatment. Numerous examinations were made during this time and numerous colon bacilli were found in the urine. There was no residual urine, the frequency was from eight to ten times daily. He was given a careful examination by a gastroenterologist, who felt that he had a colitis and advised a diet. The patient looked and felt well otherwise. A rectal examination revealed a definite infiltration in the rectovesical space and marked fulness with extreme tenderness. Cystoscopy showed a very inflamed bladder and a catheter passed up the left ureter for a very short distance. Numerous small particles of brown material were floating in the bladder, and the possibility of intestinal fistula was suspected. The patient was to go to the hospital for pyelography but refused to do so. Two weeks later he was seen by Dr. Keves who gave him a second cystoscopic examination. At that time a definite opening was noted in the region of the left ureter and a diagnosis of fistula was made. The patient was operated on by Dr. Brewer and cancer of the sigmoid was discovered. The patient left the hospital with an artificial anus and lived one year when he died of the condition. The bladder symptoms disappeared entirely on the establishment of the colostomy.

CASE 2—The patient entered the hospital because of frequency of urination and complete retention. There was from 15 to 20 ounces of residual urine. The patient was operated on for cancer of the prostate. It was noted that the prostatic growth was well encapsulated and the carcinomatous portion extended well into the postprostatic space. An attempt was made to remove this by sharp dissection and both vesicles were cleared out.

It is possible that the rectum may have been injured at the time although in the routine examination of the rectum following the operation no evidence of such an injury could

16 Personal communication to the author.

be made out. The patient returned to the ward in good condition with a retention catheter in place, and five days following the operation the presence of a superficial emphysema was noted. This gradually extended over the entire scrotum following the usual course of urinary extravasation. The retention catheter had meanwhile been dislodged from the bladder and there was a considerable leakage from the perineal wound. The emphysema finally disappeared and when the wound healed it was noticed that the patient passed a small quantity of feces through the urethra. The patient finally left the hospital five weeks after the operation, and for three years following passed gas and feces regularly through the urethra. His general health was excellent; he died of some intercurrent infection in Bermuda three and one-half years after the operation.

CASE 3—D. P. had had bladder symptoms for a period of ten years with a definitely enlarged prostate. The patient had noted an inability to empty the bladder unless sitting down, and considerable pressure was required on the perineum. Perineal prostatectomy was done at St. Bartholomew's Hospital and an enormous prostate was removed. It had previously been possible to pass the examining finger over the summit of the prostate.

The patient had a spirited convalescence and left the hospital six weeks following the operation. The residual urine never disappeared entirely, averaging from 2 to 4 ounces. A rectal examination was not made until one year after the patient left the hospital. At this time it was noticed that a definite papilloma of the anterior rectal wall was present and on prostatectomy this was made out as extending well up toward the sigmoid. The condition improved greatly on rectal irrigations but the urine began to become dirtier and a possible communication between the bladder and the rectum was suspected. Marked fulness was made out in this area and the passage to the rectum had narrowed down to the size of a small catheter. The patient refused any treatment, however, until complete retention occurred on board an ocean steamer. Colostomy was done on his arrival in New York, and the patient lived three years after this time with amelioration of bladder symptoms and a marked improvement in his health. Six months before his death the area between the bladder and the rectum broke down and a moderate fecal discharge was observed through the urethra.

CASE 4—J. H., a minister, had prostatic symptoms for a period of two years, particularly noting straining and urgency, with no great amount of residual. Cystoscopy revealed a large prostate with the bladder greatly inflamed and red in the area of the trigon. On catheterization, numerous gas bubbles followed the irrigation and the patient had also observed an occasional passage of gas through the urethra. The first stage of the prostatectomy was done and the bladder was drained for a period of six weeks. The urine had a fecal odor and methylene blue (methylthionine chloride U. S. P.) injected in the rectum appeared in the bladder urine within two or three minutes.

No evidence of a rectal or sigmoidal growth could be made out, although there was a definite narrowing of the colon in the region of the bladder and sodium iodide injected into the bladder showed evidences of filtering through into the space above and posterior to the bladder. In the operation the prostate was removed with difficulty, owing to firm fixation. The patient had a difficult convalescence and the suprapubic wall was kept open for two months following the operation. At this time the mucosa of the bladder regained its normal appearance and the bladder was allowed to close. The patient's general condition three years after the operation was good and he had no further symptoms from the fistula. A later history was obtained of proctitis and perirectal abscess due to excessive horseback riding over a period of years.

CASE 5—E. R., a Jewess, was admitted to City Hospital in poor condition. The patient was admitted to Harlem Hospital and gave a history of having been operated on three weeks previously. She had applied to the dispensary for treatment and was told that the uterus was tipped and that operation would have to be done from below to remedy the condition. This was carried out (Watkins interposition was probably done) and the patient went home two weeks afterward. She

developed mild abdominal pain, distress with frequency of urination, and pain over the bladder. Three days after admission to the Harlem Hospital she began to pass feces by the urethra, and she was sent to the City Hospital. At the time of the cystoscopy the patient was semimoribund and the cystoscopy was carried on under difficulty. Feces were passing into the bladder and the viscus was washed clear of difficulty. A loop of encrusted suture projected into the bladder anterior to the suture; a large hole was noted which discharged intestinal contents. A diagnosis of traumatic vesico-intestinal fistula was made. The patient died two days later and autopsy showed a large inflammatory mass posterior to the bladder involving the fundus of the uterus, and two loops of ileum in the bladder wall. The sutures bringing the uterus in position had apparently passed through all three structures and following the spread of infection, a fistula had developed.

40 East Sixty-First Street

ABSTRACT OF DISCUSSION

DR. FRED RANKIN, Rochester, Minn. While this bizarre pathologic condition appears infrequently, it is formidable when it does occur, is difficult to handle, and is frequently attended by high mortality and undesirable end-results. Etiologically, the enterovesical fistulas may be divided into three classes: (1) the congenital group, (2) those due to carcinoma, and (3) those due to inflammatory processes. The latter group, of course, contains the appendiceal cases, which may be divided into (1) those cases in which an acutely inflamed appendix fastens itself onto the bladder and ruptures without abscess formation or without spreading contamination into the peritoneal cavity and (2) those cases in which an appendiceal abscess necroses into the bladder and forms a direct communication between the cecum and the bladder. In my series, I am impressed by the fact that males predominate over females in falling victim to this unfortunate condition, two to one. In the first place, more men have diverticulitis of the sigmoid. In the second place, the uterus is between the bladder, the rectum and the sigmoid and makes an attachment between these organs more difficult. Diverticulitis occurs more frequently in fit short individuals who have a tendency to lead a sedentary life. Physicians seem to be especially prone to develop diverticula. Strangely enough, diverticulitis does not cause more fistulas than does carcinoma, since among my patients there were twelve cases due to diverticulitis, ten to carcinoma and four to inflammatory conditions. The operative treatment of this type of ailment is a difficult one and the tendency to operative failure both from the standpoint of immediate mortality and that of end results, as evidenced by the recurrence of a fecal fistula which drains to the outside this time, is striking. My operative mortality was approximately 10 per cent. In nine of the patients operated on two or more operations were necessary before the fistula was closed. The usual procedure in operating on these patients is a direct attack on the fistula in one stage, attempting to separate the sigmoid or cecum from the bladder and to close the two openings. Because of the amount of inflammation present, failure is frequent, and I think one may well accept Dr. Morrissey's suggestion that a primary colostomy is of great assistance. I have done this myself in three cases and I am convinced that it is a practical method. It sidetracks the fecal current and permits the infection in the bladder to be cleaned up, and in this way likewise allows the kidney infection to be taken care of.

DR. ARTHUR L. CHUTE, Boston. The published case of mine that Dr. Morrissey referred to was an interesting one, but I lost the patient. The case was striking in that the man was passing great numbers of strawberry seeds in the urine. I operated on him finding the fistula low in the pelvis and sewing it up. The man died and at autopsy I found a walled off abscess in the pelvis. I saw another case with Dr. M. H. Richardson in 1910 also reported in the paper to which Dr. Morrissey has referred. This patient was operated on twice, but there was a fatal outcome from a general peritonitis. The only case of this type in which I have had a favorable outcome was that of a patient I saw some six years ago and on whom I did a one stage operation, closing the fistulous opening in the bowel and the one in the bladder. I instituted drainage but he apparently

had a suppurative pericystitis and had to have a lot of drainage for a long time. I had to open up the perineum, but he finally made a good recovery. Those are the only three operative cases that I remember to have seen, though I recollect a woman with this condition who refused operation and who died a short time afterward, but I think of some intercurrent trouble. Dr. Morrissey's suggestion that drainage be done preliminary to operation is very important and should be carried out.

DIAPHRAGMATIC HERNIA IN A CHILD, AGED ONE YEAR

P. L. TRUESDALE, M.D.

FALL RIVER, MASS.

The increasing number of cases of diaphragmatic hernia reported in recent literature suggests unusual vigilance in detecting this deformity. Nevertheless, its appearance in children under 10 years of age is still considered rare. Apparently this is more indicative of the difficulties of recognition than of the infrequency of occurrence. However, Dodds and Flew¹ roentgenographed every child born in the obstetric hospital in London over a period of eighteen months and found only one case of congenital diaphragmatic hernia in 800 cases, and only one case in 200 postmortem examinations. In Greenwald and Steiner's² series of eighty-two cases in children aged up to 10 years, (1912-1928) only twenty-five were recognized during life. Eleven were operated on, six patients died after operation. Of the five that recovered, two had gastro-enterostomy because in each case it was found impossible to reduce the stomach. Parenthetically, gastro-enterostomy can serve no useful purpose when the stomach is involved in the hernia because the stoma is made in the chamber below the aperture in the diaphragm.

Aue,³ Speik,⁴ Goetsch,⁵ Behrend,⁶ Bettman and Hess,⁷ McFadden,⁸ O'Connell⁹ and Sanders¹⁰ each report a case in which recovery followed operation. Aue operated successfully on a boy, aged 9 years. He also operated on a girl, aged 5 years, who had a recurrence three months later, the parents refused operation a second time and the child died two weeks later from intestinal obstruction. Woolsey¹¹ operated successfully on an infant, aged 35 days, but the child died in one year from acute intestinal obstruction due to a recurrence of the hernia. Brown¹² reports one case and Carman¹³ reports two cases in which operation was performed with fatal termination a few hours after the operation. The three patients, two aged 5 years and one aged 9 years, died from "shock." Thus far, the total number of patients under 10 years of age appearing in the literature as operated on reaches twenty-two, with a total mortality rate of 41 per cent. This rate does not include the two fatal cases from recurrence.

My reported cases have been overlooked by Greenwald and Steiner. Including recurrences in the first patient, I have had seven consecutive cases in which no deaths occurred after operation. For comparison, in 1912 the operative mortality reported by Scudder¹⁴ was 75 per cent, high, because most operations were undertaken for the relief of intestinal obstruction.

A recent case in my series is remarkable because of the extreme youth of the patient and her rapid and uneventful convalescence, which was due, in part to operation undertaken while her condition was good.

REPORT OF CASE

P. L., a girl, aged 1 year, admitted to Truesdale Hospital June 15, 1930, had been delivered normally as the result of her mother's third pregnancy. For seven months the baby seemed well. In January, 1930, she had a slight attack of

Fig. 1—Appearance before operation. A cardiac area (dextrocardia). B right side of diaphragm. C left side of diaphragm. D herniated portion of stomach.

bronchitis, which lasted for two weeks. During this interval the mother heard rumblings and gurglings in the child's body. Believing that this indicated only an unusual degree of gastric fermentation, she felt no particular concern. When 9 months old the child had a digestive upset and refused her feeding. Two weeks previous to admission to the hospital the baby had a severe crying spell, wanted to be held, and refused to lie down. Dr. A. E. Parkhurst of Beverly, Mass., after a complete examination, established the diagnosis of diaphragmatic hernia.

The child had the appearance of a fairly normal baby and weighed 18½ pounds (8.5 kg). With the exception of the thorax, the general physical examination was negative. The cardiac area of dullness extended 4 cm. to the right of the midsternal line. On inspiration a sound vibration was perceptible when the hand was placed lightly over the epigastrium. There was slight dullness over the left base. On inspiration a sound resembling that of bubbling water was heard with the stethoscope over this area. Sometimes this sound was so audible that it could be heard anywhere in the room.

After a barium meal a roentgen examination was made and a diaphragmatic hernia was revealed in the left side with

most of the fundus of the stomach in the thorax and the heart displaced to the right. A barium enema excluded the colon. The diagnosis of congenital hernia of the stomach through an opening in the left side of the diaphragm was confirmed.

A few days were necessary for the patient to recover from the fatigue of examination and to reestablish her normal body functions. During this time a thorough evacuation of the barium from the intestinal tract was obtained. June 21, 1930, the operation for repair of the diaphragm was carried out as follows:

The patient was placed on the right side and the left arm was extended over her head. An intercostal incision was made extending through all layers of the thoracic wall, including the pleura. The incision began 2 cm. from the left border of the sternum, it was first carried downward and then along the course of the eighth interspace to the posterior axillary line, where it was directed upward to form a lapel. The upper rib was divided at each end of the incision, the rib flap being turned upward. At this point the anesthetist allowed the lung to remain partially collapsed. This exposed the

Fig. 2—Appearance after operation. A cardiac area (normal). B right side of diaphragm. C left side of diaphragm. D stomach in normal position below the diaphragm.

hernial opening, a para-esophageal aperture, through which the upper two thirds of the stomach and the spleen had passed into the thoracic cavity. There was no sac. If there was one originally, its membranous covering had ruptured, collapsed and was not discernible. Now it was the picture of a false congenital hernia. The edges of the hernia were raised by grasping the margins with Allis forceps. The stomach and spleen were replaced within the abdominal cavity without difficulty. The opening in the diaphragm was closed by five interrupted double-strand sutures of number 5 silk. The suture line was reinforced by single-strand sutures of silk which were placed between the first sutures. Further examination of the diaphragm showed a second defect about the size of a half-dollar (30 mm.) in the anterior and central area of this leaf at the foramen of Morgagni. There was only a thin, serous membrane of pleura covering this defect of the musculature. This area was repaired by infolding the serosa with interrupted sutures of single-strand number 5 silk.

The wound in the chest wall was closed by restoring the divided rib to its normal position and holding it in situ by interrupted sutures of number 2 chromic catgut. The muscles

of the chest wall and their fascia were also sutured, this time with a running stitch. As the final loop of catgut was inserted to close the pleural cavity, the lung was fully expanded. The edges of the skin were united with a continuous lock-stitch of horsehair. The whole wound was reinforced by the use of five silkworm catgut sutures. The patient entered the chest cavity in the ninth interspace and emerged at the seventh.

Immediate postoperative recovery was good. The first day after operation the child's temperature rose to 103 F with respirations at 44. She took fluids well, however. A physical examination failed to reveal any evidence of fluid in the left pleural cavity. The roentgenograms taken five days after operation revealed a shift in the position of the heart toward its normal position and the stomach in its normal location below the left diaphragmatic arch. There was no evidence of fluid.

The baby's convalescence was uneventful. She took nourishment well and appeared to have very little discomfort after the first day. Ten days after operation she was transferred from the hospital to her home, a distance of 70 miles, without incident. The wound had healed by primary union.

In view of this experience and of past observation it is clear that the lives of infants and young children should not remain in jeopardy from failure to deal with hernia of the diaphragm by operation. In a series reported by Woolsey,¹¹ two infants out of twenty-four children were operated on successfully at 31 months and 35 days, respectively. The author says:

Of these twenty-two, at least seven, in none of whom diagnosis had been made, could have been operated on; possibly their lives might have been saved, and seven others of the twenty-two, also without diagnosis, and therefore proper treatment, might have had their lives prolonged if the operation performed later.

When the dangers of unilateral intrathoracic pressure are given careful consideration during operation, the little patients withstand the technical stage of closing the aperture in the diaphragm remarkably well.

The diagnosis of diaphragmatic hernia appears to be more difficult than the operation for its cure. It is necessary to draw on the imagination to realize that respiration and circulation must be greatly embarrassed by the presence of distended stomach and colon in the pleural cavity, with the collapse of one lung and encroachment on the other by displacement of the mediastinum. The heart and lungs must yield increased pressure from the transposed hollow viscera. The volume of space in the pleural cavity which a distended stomach alone can occupy is sufficient to cause death from asphyxia. Such a case was reported by Gibson¹⁵ of Cleveland. Precordial distress, dyspnea, cyanosis, and cough always irregular in time and severity are circulatory and respiratory manifestations of diaphragmatic hernia. Gastro-intestinal symptoms are indicated by interference with the motility of the stomach and intestine when the organs are involved in the hernia. A great variety of symptoms indicating digestive disturbances may simulate peptic ulcer, gall stones, pancreatitis, appendicitis, intestinal stasis and obstruction. A dextrocardia often serves as a key to the diagnosis.

The Galvanic Current—According to Turrell, the therapeutic effect of the galvanic current is due simply to the heat generated in the tissues and the increased functional activity from the bombardment of the tissue cells.—Shaffer, L. W. *Arch. Dermat. & Syph.* February, 1931.

SYMPATHETIC RAMISECTION IN
SPASTIC PARALYSIS

END-RESULTS OF SIXTY CASES *

W B CARRELL, M D

DALLAS, TEXAS

Influenced by the clinical results and the very plausible explanation of sympathetic release, reported by Royle¹ and supported by Hunter,² my colleagues and I have performed ramisection for spastic paralysis in a sufficient number and variety of cases to make a report of them of some value in arriving at a proper estimate of the operation.

Included in this study are eighty-three ramisections: twenty-three cervical and sixty lumbar, with twenty-five left, fifteen right and eleven bilateral. The first analysis was based on the comparative study of a group of operations done in 1925, including twenty lumbar and four cervical operations, another in 1926 and 1927 with sixteen lumbar and six cervical, and a third group in 1928 with twelve lumbar and thirteen cervical operations.

In 1925 the indications specified by Royle in selecting cases were followed closely and only those patients were operated on who had fair cortical control, definite increase in plastic tone, with slow joint position change and hung up reflexes. The average age was greater than in the 1927 or 1928 group. In the latter two groups the mental requirement remained the same, but the state of the muscle tone was not given consideration in the selection of cases. The operative technic was alike in the three groups and the final results were so nearly the same that grouping in this manner offers only one conclusion, namely, that increased plastic tone has no value in selecting cases for operation. This is in accord with the experience of Von Lackum.³

In our series there are seventeen left and fifteen right hemiplegias, eleven paraplegias, fifteen tetraplegias and two triplegias. The cervical operations were done through exposing the brachial plexus and cutting the sympathetic trunk to the fifth, sixth, seventh, eighth, and first dorsal nerve roots. The stellate ganglion was not exposed at any operation. Increased warmth was noted in 40 per cent, but was never so much as present in the lumbar cases.

For the lumbar sympathetic, the trunk was exposed through a lumbar incision and the gray rami from the second through the fifth, and the trunk divided below this point. Postoperative increase in the temperature of the leg was recorded in 100 per cent of the cases. In some an increase in warmth and circulatory tone was present four years after operation. In one case, twelve months later there was an increase of one-half inch in circumference of the calf on the limb that had been operated on and, incidentally, relief during the entire period from a troublesome constipation, existing for several years, by purposely dividing the trunk at the first lumbar enlargement.

Great difficulty has been experienced in making an accurate estimate of the actual effect of ramisection on the final result when a combination of measures has

been followed in treatment of the patients. Primary interest, naturally, was in improving the function of an arm or a leg and frequently the opportunity for watching the effect of ramisection alone was sacrificed by adding other operations. On several occasions a ramisection was done on one side and Stoettel's operation on the other leg with conclusions reported relative to the comparative results. Likewise, we have done stabilization in the feet, Stoettel's operation on both legs, and from twelve to eighteen months later a bilateral ramisection, with notes crediting each operation with a proportionate effect. The methods followed in determining results are open to criticism, because they are lacking in physiologic analysis, but from a practical application they have seemed to convince those working with the cases that a reasonably accurate conclusion may be obtained. A patient who can walk better, can step over objects, climb steps, stand on one leg, pedal a sewing machine and do similar coordinating movements that he could not do before operation is classified as improved and is graded accordingly. While it is true that spastic children above 10 or 11 are optimistic in their attitude following any procedure, we have found that their reaction after twelve or eighteen months combined with that of the parents and friends coincides closely with the estimate independently made on our records.

Examinations did not reveal any difference in the character of reflexes before and after operations. Those patients having a typical hung up knee reflex had approximately the same after operation. It was not possible to observe any difference in the height of the jerk or appreciable variation in the clonus when present. There was noted, however, in cases having most improvement a relative increase in active joint range. This can be measured with fair accuracy at the knee by placing an extensoflexometer on the joint with the patient in a sitting position and measuring the degrees covered in a given length of time, controlled by a stop watch. A practical test is to have the patient move the knees through their greatest range in an easy manner ten times, and it may be found, for instance, that he moves from 160 degrees to 100 degrees ten times in ten seconds. After operation he may do from 170 degrees to 98 degrees ten times in six seconds which shows an increased amplitude and better control of antagonistic muscles.

The record of footprints has not in our cases given any particular information. The entire appearance of the imprint can be changed by increasing or decreasing the speed of walking or otherwise instructing the patient and it has therefore seemed difficult to enforce the same conditions after operation for accurate comparison. Steindler⁴ has done some work with action currents and this may prove a valuable method in making positive physiologic study on the muscles that have been operated on. There was found a change in the frequency and amplitude not observed in the normal muscle.

No change was observed in fixed contractions or in those contractions which develop on attempting motion or excitation, as in the scissor gait equinus or valgus in the foot. Relief of the contractions by other operations has been necessary, but it has been noted that a paraplegic of equal spasticity has better function in the leg with lumbar ramisection and section of the obturator, than with obturator section alone. Three of our

4 Steindler, Arthur. Alteration of the Action Current of Skeletal Muscles Following Sympathetic Ramisection. J. Bone & Joint Surg. 11: 1 (Jan.) 1929.

patients with paraplegia were identical in deformity and gait. Hips and knees were flexed, the feet were in valgus, there was moderate equinus, and they walked poorly with a labored shuffling gait. This type is fairly common and the posture is due more to muscle weakness than to contractures. Ramisection in these cases was of no value, although a bilateral operation was done in one of them.

Contrary to the experience of Von Lackum³ and Stewart we have never observed an appreciable improvement immediately after the operation. The patients were frequently kept several weeks in the hospital before being sent to the gymnasium, and there is no record of favorable changes before exercises were started. With the advent of gymnasium work there was better response in many cases than that shown in the gymnasium during a test period before operation. In most instances the patients were given supervised exercises beginning on the tenth or fifteenth day and continued from two to three weeks. On readmission after three months they again had supervision for a few weeks, and during the first or second return admission improvement would be noted at first and would generally reach a maximum by the end of twelve or eighteen months. The work in the gymnasium undoubtedly adds a considerable measure of improvement but it cannot be credited with all the results, for in many instances the same care and time have been given prior to operation without appreciable effect but with definite rapid improvement after ramisection. Exercises seem most effective when started some weeks after the operation. Patients are returned for training the short time before discharge, for its value during the stay at home, while waiting for the three months' period admission when it is expected a more satisfactory training schedule may be instituted.

Twenty patients in the series had other operations, some before ramisection a few at the same time, and others after evaluating the effect of sympathetic denervation. These operations were in the nature of multiple Stoeffel's operations or subastragaloid stabilization. Although it is difficult, one may distinguish between results following these operations and those from ramisection. In the latter case, as expressed by many of the older children there is an added feeling of security in standing or walking. The improvement relates more to coordination and equilibrium. The range of knee motion is greater in walking. Movements in the spastic extremities are smoother and more easily carried out. In the tables indicating percentage of improvement, deductions have been made for that due to contributing operations, and in some cases, no improvement is recorded for ramisection, from 25 to 40 per cent is elsewhere credited to these operations. Likewise there are some with a slight percentage for ramisection and are elsewhere given a higher percentage of improvement for gymnasium training.

From our experience with the treatment of spastic paralysis, were it necessary to choose between ramisection and Stoeffel operations with foot stabilization the latter two procedures would be regarded as meeting more indications and giving a higher percentage of improvement in a large group of cases. It is our purpose however, to credit ramisection with whatever of value there may be in it, and to that end groupings have been made for analysis of certain factors that may influence the result of operations.

It must seem obvious that any operation designed to cut the pathways of unfavorable impulses to voluntary muscles should be carried out before excessive damage has been done. Von Lackum recognized that ramisection at an early age, before the pattern of deformity had been established, gave better results than the same operation done late. In our series, the lumbar cases grouped according to the age at the time of operation gave the results shown in table 1.

TABLE 1—Percentage of Improvement Following Ramisection

Number of Cases	Age	Mentality	Percentage Improvement
7	10 to 17	71	1
10	5 to 10	74	14.5
15	11 to 17	73	2
7	14 to 17	70	0

Before making any interpretations from this table, it will be interesting to know whether the figures are influenced by other factors.

The groups presented in table 2 suggest, at least that the age of the patient and the type of plegia are of less significance than severity of the lesion and mental development. Of the fifty-one cases with sixty-two lumbar operations the average gain is 16 per cent. In fourteen cases, no gain is recorded and twelve cases had 25 per

TABLE 2—Factors Influencing Improvement

Number of Cases	Type of Deformity	Average Age	Mentality	Percentage Improvement
5	Left hemiplegia	10.2	73	1
11	Right hemiplegia	10.4	72	1
	Paraplegia and tetraplegia	12	71	1

cent or more. A detail of these two groups is illuminating (table 3).

One must conclude from analysis of these cases that severity of physical disability and the mental development are the two important factors influencing the progress after operation. It is recognized that extreme disability is always more difficult to influence favorably in treatment but if ramisection produces results by release of impulses affecting striated muscle, even in severe cases with poor cortical control there should be some evidence of changed reactions. None were

TABLE 3—Comparison of Cases Showing Gain and Those Not Showing Gain

No gain (14 cases) Above 25 per cent gain (12 cases)	Age	Mentality	Gain
10.4	71.4	41.4	
10.2	71.4	41.4	

observed in the fourteen cases of this group. It is noteworthy to observe a high percentage of improvement in cases having ramisection on both sides. There is apparently an added value to the first. No effect, however, was apparent in the leg that had been operated on when a cervical operation was done nor to the arm when a later operation was done on the lumbar sympathetic. In twelve cases ganglionectomy was substituted for ramisection and comparison showed slightly better results.

The twenty-three cervical cases have been disappointing in general results. At operation the ram were clearly exposed and avulsed. The stellate ganglion was not removed nor was any attempt made to find the branch, from below joining the first dorsal, as described by Kuntz.⁶ The postoperative temperature was slightly

5 Stewart, S. F. End Results of Ramisection in Spastic Paralysis. J. Bone & Joint Surg. 9: 24 (Oct.) 1927.

rured in ten, was marked in three and was not appreciable in ten cases. Eleven cases were not improved by operation, six showed from 10 to 15 per cent and five showed from 25 to 40 per cent improvement. The poor results in this group may come from imperfect operative technique or may be influenced by inadequate postoperative gymnasium work. The latter is true; it might be argued, because after all, most of the good results are due to enthusiastic postoperative training, but it is not in accord with the unprejudiced study made of this series during the past five years.⁶¹

The improvement has not been great and may be duplicated by other measures, yet there is something definitely useful in ramisection which may be added to but not substituted for other procedures in the treatment of spastic paralysis. From 10 to 25 per cent improvement would not appeal to one treating most chronic disabilities, but one is thankful for small gains in spastic paralysis.

EXPERIMENTAL WORK

Operation.—In the early part of 1927, in conjunction with Dr. Fred F. Rogers, physiologist at Baylor University College of Medicine, an attempt was made to duplicate the work of Royle. Six goats were operated on by removal of the left sympathetic trunk, and to obviate any chance of error through irritability about the lumbar muscles from scar tissues each goat was operated on thirty days later on the right side to the extent of exposing the sympathetic trunk but not touching or otherwise damaging it.

Observations.—After recovery from operation no limp or other variation in behavior was noted. At the second operation one month later during the process of anesthetizing rigidity was studied but was so variable in character that it was impossible to note any constant difference in the extremities. Decerebration by transection was done at varying intervals of 60 to 120 days after ramisection. It was found that marked variation existed in the character of rigidity. Two

specimens exhibited identical changes at the examinations, described in Royle's experiments. One had just the opposite reaction, the leg on the side operated on remained rigid and the mate was more flaccid and fell quickly from the position imposed on it. The other three varied in reaction at each of several examinations and could be influenced by posture of the head or changing body position. The observation period covered from three to twelve hours. Postmortem examinations confirming the completeness of sympathetic removal were done in all animals. The conclusion was that on goats, previous sympathectomy does not influence the rigidity of decerebrate specimens.

This was not in accord with the experiments that formed the basis of Royle's clinical work which was shown so convincingly to American surgeons a few years ago. His clinical results and those later of Von Lickum and Stewart are notably good, though the explanation for it appears to be erroneous. Sherrington,⁷ in a study of decerebrate specimens, has described the lengthening and shortening reactions in muscle whereby it maintains any constant length against varying tension. Sherrington⁷ found that the reflex for this tonic contraction existed in the muscle and termed it the myotatic reflex. He thought it was controlled by a somatic efferent impulse and not by the sympathetic as believed by Langlaan,⁸ de Boer,⁹ Royle and Hunter. This holding mechanism proved in smooth muscle and suggested for skeletal muscle by Frohlich and Meyer¹⁰ and by Plant,¹¹ is accepted by Hunter who regards it as plastic tone and through sympathetic control is responsible for the shortening and lengthening reactions of Sherrington. Boeke,¹² Garven,¹³ and Coates and Tiegs¹⁴ have disproved this theory. Muscle shows a marked initial resistance when stretched from any given position, and with increase in stretching there is less resistance developed. This element of tone studied by Rieger¹⁵ and Spiegel,¹⁶ is called the brake mechanism and was found to be influenced by the sympathetics in the work of Kuntz and Kerper.¹⁷

Forbes and Cobb¹⁸ and others are convinced that the entire phenomenon of muscle tone can be explained by the phasic reactions in the simple muscle twitch built up by rhythmic contractions, and they see no reason for dividing muscle tone into two elements, plastic and contractile. They, with Pollock Kanavel and Davis¹⁹ were unable to find any sympathetic influence on muscle tone.

The other view on tonic contractions held by some investigators is that a passive state of contraction is superimposed on the ordinary muscle contraction. In this tonic contraction there is diminished or absent action currents and absence of fatigue. Those accepting

this view are not in agreement with regard to sympathetic influence. The preponderance of evidence favors subservance of muscle tone through spinal pathways, and not under sympathetic control, irrespective of basic differences in conception of muscle tone.

Coats and Tiegs repeated the experiments of Royle and Hunter on fowls and goats and could not corroborate their results, but they did find that muscles deprived of sympathetic control were much more easily fatigued than the normal muscle. This is in accord with the work of Gruber,²⁰ who was able to stimulate fatigued muscle with epinephrine, and of Orbelli,²¹ who could do the same by stimulating the sympathetic supply to the muscle. It is established that skeletal muscle has a dual nerve supply, spinal and sympathetic. There is a marked variance in opinion as to the nature of tonic muscle contractions, but the mass of evidence favors somatic and not sympathetic nerve influence controlling it. Exceptions to this are found in the work of Kuntz and Kerper, experimenting with dogs which corroborates some of the work done by Royle and Hunter. The most definitely proved factor of the sympathetic relation to skeletal muscle is shown in the work of Gruber, Orbelli, and Coats and Tiegs regarding its influence on fatigability. If the sympathetic function is to conserve the strength in muscle and prevent fatigue, the prolonged irritability from continuous impulses could conceivably result in a state of contraction, which might influence unfavorably the existing disability in spastic paralysis.

RATIONALIZING THE SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM *

W. K. LIVINGSTON, M.D.

PORTLAND, ORE.

In 1878 Claude Bernard¹ called attention to the remarkable constancy of body fluids and predicted that the delicate adjustments necessary for the maintenance of internal harmony and economy must be dependent on nervous regulation. Today that prediction promises fulfillment. In spite of the present confused state of knowledge in this new field of study, evidence is accumulating that in the region of the hypothalamus there are visceral centers exerting a control over water balance, the metabolism of fats and sugars, vascular adjustments (perhaps even the activities of capillaries and sweat glands), regulation of temperature, and a balanced control of glandular secretions and smooth muscle tonus changes in the internal organs. Evidence is accumulating to indicate that the visceral nervous system, which is the intricate network of neurons by which these activities are affected, regulates and, in turn, is affected by the pH of body fluids, influences and expresses the activity of certain glands of internal

secretion, controls the mobilization of leukocytes and other cytologic defense mechanisms, has some relation to the formation of antibodies, and is important in the changes associated with protein sensitization and anaphylactic shock.

Further, it is known that this system is capable of abnormal activity in any of its several divisions and that the upsetting of the delicate internal balance which follows this disturbance of function may provide the underlying cause or at least prove a contributing factor in the development of certain clinical syndromes, such as thyrotoxicosis, diabetes and peptic ulcer.

THE VISCERAL NERVOUS SYSTEM

The visceral nervous system is an elaborate and complicated network of neurons over which are conveyed impulses to and from brain and spinal centers that affect the function of glands and smooth muscle in all parts of the body. It is made up of two primary divisions, the *craniocervical*, or *parasympathetic*, division and the *thoracolumbar*, or *sympathetic*, division. These two divisions appear to be antagonistic to each other and maintain normal function in the organs they supply by a delicately balanced control.

At the present time, interest centers in the sympathetic division. There are numerous reasons for this: first, the evidences of overactivity of portions of this division are coming to be recognized, second, its peripheral pathways are relatively accessible to surgical attack, finally, no dangerous after-effects have been noted following surgical removal of parts of this division.

THE SYMPATHETIC NERVOUS SYSTEM

Arising from cells in the lateral column of gray matter in the spinal cord from the first thoracic level above to the second lumbar level below are neurons termed "preganglionic neurons," over which must pass all those impulses expressing the functions of the "lumbodorsal outflow" which are termed the sympathetic nervous system. The fibers of these preganglionic neurons leave the cord by the anterior roots and enter the sympathetic chain of ganglia by way of the white rami communicantes, where they turn upward or downward for varying distances to end in a sympathetic ganglion. Here they are in synaptic relation to postganglionic neurons which leave the primary chain to pass by various pathways to the smooth muscle or gland that they supply. The postganglionic neurons that supply visceral tissues in peripheral parts of the body turn back from the ganglionic chain by way of the gray rami communicantes to join the spinal nerves and from them are distributed segmentally to the blood vessels, sweat glands and erector pili muscles.

POINT OF SURGICAL ATTACK

The ideal sympathectomy would consist of a selective division of all the postganglionic neurons that supply a particular part of the body. In the case of an internal organ the pathways of these neurons is so complicated that it is customary to interrupt them surgically near the organ itself. A partial sympathectomy is accomplished by stripping off the plexus of fibers around the main artery of supply to the organ. Such a procedure doubtless also interrupts parasympathetic fibers and has the added disadvantage of being an incomplete denervation.

In the case of sympathectomy for an extremity the problem is still more complex. It is obviously impossible to divide sympathetic neurons after they have

reached the spinal nerves. A partial sympathectomy is accomplished by periarterial sympathectomy, or the removal of a short portion of the artery. These procedures may have limited indications but are objectionable because of the very incomplete denervation that results and the impermanence of the result. A more complete division can be accomplished by cutting the gray rami, but the usual operation consists in excision of sympathetic ganglions so as to prevent impulses from the preganglionic neurons reaching the postganglionic. The chief objection to this operation lies in the fact that large areas beyond the part selected for denervation are robbed of their sympathetic supply.

Thus, the removal of the upper two thoracic sympathetic ganglions for the cure of Raynaud's syndrome affecting an upper extremity also affects the head and neck and important thoracic viscera. The customary excision of the second, third and fourth lumbar ganglions in the treatment of lesions involving the lower extremity affects pelvic and lower abdominal viscera as well.

The advantage of these two operations is that they result in a more complete interruption of sympathetic pathways than can be secured by other procedures, and in the cases treated in this fashion no serious after-effects have been observed.

Chart 1.—Skin temperature after injection with procaine hydrochloride in Miss G. R., aged 23 with chronic arthritis: solid line left toe; broken line right toe; constant temperature reading 30°C (86°F); needle reading —5°. In the charts the time of injection is indicated by an arrow.

SURGICAL TREATMENT OF CLINICAL SYNDROMES

The earliest operations performed on the sympathetic nervous system for the relief of asthma, exophthalmic goiter and angina pectoris have fallen short of expectation in their results. They demonstrated, however, what has been recently clearly indicated by the work of Cannon,³ that visceral tissue is capable of continuing a fairly normal function even in the absence of portions of the sympathetic chain.

More recently Royle⁴ has advocated sympathectomy for spastic conditions of skeletal muscle. I think it may be said that in this particular field the results have again fallen short of what has been hoped. There have been cases that have shown clinical improvement after operation, but results have not been constant and Royle's interpretation of his results have not been accepted by physiologists.

At the present time many of the best surgeons are attacking a wide variety of clinical syndromes by sympathetic ganglionectomy. The diseases so treated

make up a surprisingly heterogeneous assembly, yet analysis reveals certain common characteristics that permit of an approximate classification into three groups.

In group 1 are listed those syndromes in which the visceral pain is the major characteristic:

- 1 Angina pectoris
- 2 Painful amputation stumps
- 3 Tabetic crises
- 4 Causalgia
- 5 Inoperable carcinoma
- 6 Dysmenorrhea (?)
- 7 Gastralgia (?)
- 8 Trigeminal neuralgia (?)
- 9 Nephralgia (?)

In group 2 occur those gastro-intestinal disturbances which it seems reasonable to ascribe to overactivity of the sphincter muscle:

- 1 Hirschsprung's disease
- 2 Pyloric stenosis
- 3 Intussusception
- 4 Cardiospasm
- 5 Globus hystericus (?)
- 6 Spastic constipation (?)

In group 3 are found a variety of clinical syndromes whose single striking characteristic is a functional limitation in blood supply:

- 1 Raynaud's disease
- 2 Scleroderma
- 3 Acrocyanosis
- 4 Chronic arthritis
- 5 Chronic ulcerations
- 6 Spastic paralyses
- 7 Endarteritis
- 8 Retinitis pigmentosa
- 9 Vulvar kraurosis

A WORKING HYPOTHESIS

I have long contended⁵ that spasm of smooth muscle of blood vessels is capable of giving rise to pain in exactly the same way that spasm of smooth muscle of the gastro-intestinal, urinary and biliary tracts may furnish adequate stimuli for pain. It seems to me to be probable that angina pectoris, causalgia, the pain associated with Raynaud's disease and certain cases of painful amputation stump may all be due, either directly or indirectly, to abnormal changes in tonus of blood vessels.

If, then, it is possible to explain the pain syndromes as due to abnormal tonus of vessels, the gastro-intestinal group to overaction of sphincters, and the third group to reflex diminution in blood supply, it is immediately apparent that all three groups have a single common characteristic—spasm or hypertonus of smooth muscle.

Physiologists have long taught that one of the primary functions of the sympathetic nerves has been to subserve tonus of smooth muscle and are coming to recognize that in human beings an overactivity of certain parts of the sympathetic nervous system may be expressed as spasm or hypertonus of smooth muscle. Thus there is a physiologic explanation of these apparently heterogeneous clinical syndromes, and a logical answer as to why sympathectomy may result in improvement. While my own experience has been limited those cases I have seen which appear to have been benefited by sympathectomy show results that may be reasonably explained as due to a release of hypertonus or spasm of smooth muscle. Doubtless there will be

³ Cannon W. B., Newton H. F., Bright E. M., Menkin V. and Moore R. M. Some Aspects of the Physiology of Animals Surviving Complete Exclusion of Sympathetic Nerve Impulses. *Am. J. Physiol.* 89: 84 (June) 1929.

found exceptions to such a sweeping statement, but, until it is possible to ascribe to the sympathetic nervous system functions that the physiologist is not now able to credit it with possessing it seems that this simple explanation should be adhered to

CHRONIC ARTHRITIS

The characteristic functional limitation in blood supply said to be common to group 3 is not always immediately apparent. At first glance, chronic arthritis might appear to be an exception. However, close study of patients with chronic arthritis reveals that many of them exhibit cold, pale and clumsy extremities in addition to the arthritic changes. It is true that there are cases of this disease in which such superficial evidences of limited blood supply do not exist, but it is significant that almost without exception the cases that are benefited by sympathectomy are those in which these conditions are present before operation. That the change in the joints might also be due to a restricted blood supply has been suggested by Bankart.⁶ He says: "During life the joints are not passive pieces of mechanism but living structures which react to use like other living tissues. Every functional use of a joint is in a sense an injury, that is friction and pressure tend to wear

Chart 2—Skin temperature after injection with procaine hydrochloride in Miss M. D. aged 33 with arthritis deformans. Solid line, left toe; broken line, right toe; constant temperature reading, 31°C (88°F); needle reading — 42.

away the opposed articular surfaces. This normal wear is at once made good by an increase in blood supply and nutrition which always accompanies function in normal tissues, hence the balance between wear and repair is dependent on an adequate vascular response to function. If not balanced there is a wearing away of the surfaces, and products of degeneration give rise to irritation which makes itself evident in hypertrophic changes at the periphery where the blood supply is sufficient. Thus the characteristics of osteo-arthritis are degeneration leading to atrophy, erosion and eventual disappearance of the cartilage of the joint and hypertrophy leading to the formation of osteophytes at the periphery."

In one of my cases of chronic arthritis in which a unilateral lumbar ganglionectomy has been performed, the circulation in the foot on the side that was operated on is so much improved that the temperature of the skin remains 8 degrees C. warmer than the other foot during exposure. With this improved circulation there has been a lessening of deformity, a return of the ability to move the ankle, which had been absent for two years, and a sense of warmth and comfort in the entire extremity. Observations of this kind would

seem to confirm the hypothesis that vascular spasm is at least a contributory factor in certain cases of chronic arthritis.

ENDARTERITIS OBLITERANS

The casual observer might have even greater difficulty in understanding the relation of smooth muscle spasm to obliterative lesions of arteries. In cases of this type, attention has been so engrossed with the condition of the larger vessels that a consideration of the functional condition of the vascular bed of smaller vessels and the possibility of a concomitant vascular spasm has been relatively neglected. I am convinced that obliterative changes in an artery and a functional spasm are frequently interdependent.

When an artery is in spasm there is of necessity a slowing of the blood stream in its lumen and perhaps a limitation of blood supply to its own wall as a result of its strong contraction. Long continued or frequently recurrent spasm might well lead to degenerative changes in the wall of the artery, or conduce to an increase in obliterative lesions already present. It is of interest in this connection to note that patients suffering from Raynaud's disease usually give a history of early attacks characterized by extreme pallor, considerable pain and unsatisfactory circulation between attacks. Later it is noted that the pallor is replaced by cyanosis, the attacks may be precipitated by other conditions than cold and a more or less constant impairment of circulation is present. In these late cases degenerative changes in the digital arteries may be demonstrable. Sir Thomas Lewis considers cyanosis rather than pallor to be characteristic of Raynaud's disease and believes that the degenerative changes in the peripheral vessels are the primary cause of the attacks. Most observers, however, feel that the attacks are due to reflex disturbances and consider the changes in the vessels to be secondary or late effects.

Not only is vascular spasm conducive to organic change but the presence of organic change may be a cause of spasm. Sudden obliteration of an artery may be followed by sudden constriction peripheral to the obstruction. Thus, in a case of embolus in a femoral artery I noted that the distal portion of the artery was contracted to a firm, pale, cord-like state. Dr. Charles Lund of Boston tells me that in four cases of arterial embolus for which he has performed an embolectomy the artery was in spasm beyond the obstruction in each case and that observation of the leg after operation seemed to indicate that the spasm persisted for some time after the embolus was removed. It is difficult to explain such observations unless it be assumed that the presence of the obstruction or a sudden ischemia of the vessel wall results in a reflex spasm. Anything that interferes with the nutrition of the vessel musculature may lead to spasm and it is reasonable to assume that lesions in the lumen of arteries may be a cause for an associated spasm or hypertonus. Whether or not this assumption is accepted the fact remains that many cases of obliterative disease of the arteries show an additive element of spasm. Of course, there are cases that have only obliterating lesions present, but these cases do not yield to sympathectomy. It is only those cases of endarteritis in which vascular hypertonus or spasm is present that the surgeon feels justified in submitting to operation. The problem that confronts the surgeon is how to differ

⁶ Bankart, A. S. B. Chordotomy in the Treatment of Osteo Arthritis of the Hip. *Lancet* 2: 378 (Aug. 24) 1929.

⁷ Lewis, Thomas. Experiments Relating to the Peripheral Mechanism Involved in Spasmodic Arrest of the Circulation in the Fingers. A Variety of Raynaud's Disease. *Heart* 15: 7 (Aug.) 1929.

entire and estimate the relative importance of these two factors in a given case

Sympathetic ganglionectomy is a major procedure requiring precision and skill. Before submitting his patient to this procedure the surgeon must be convinced that the patient will withstand a major operation and in addition, must conscientiously attempt to answer three questions:

1. How much reflex vascular spasm is present in this case?

2. What ganglions must be removed to release the vessels involved?

3. Have organic changes progressed to a degree that will obviate a good result?

METHODS TO OBTAIN A PROGNOSIS

Before seeking an answer to these questions it is of interest to note that most of the patients in this field of surgery seek symptomatic relief by the use of local heat. They usually state that their local lesions and symptoms improve during attacks of fever. Experience has further taught that any method favoring hyperemia may prove of benefit. This may be achieved by counter-irritation, local heat, constrictive hyperemia treatment, protein shock, spinal anesthesia, natural sleep or general anesthesia.

These observations suggested two methods for obtaining a prognosis. The first method is known as "oscillometry."⁸ A rubber cuff placed around the involved extremity at various levels is inflated sufficiently to transmit pulse oscillations to a movable needle or a pen writing on a revolving paper disk. Cases with vascular spasm may show an abnormal restriction in the amplitude of pulse oscillation, particularly after exposure to cold. A marked increase in the swing after a hot bath is interpreted as indicating that the vessel is capable of dilatation and argues against advanced occlusive disease. This method has many faults, chief among which is the fact that it measures only the changes in the large vessels and gives no information as to the functional condition of the vascular bed. It is of limited value.

A better method is the so-called fever test.⁹ This consists in the production of an artificial fever by the injection of typhoid vaccine or antigen and the accurate measurement of changes in mouth and local skin temperatures. The rise in skin temperature of the involved extremity is divided by the rise in mouth temperature to obtain a "vasomotor index." Thus a patient showing a rise of 12 degrees in the temperature of a toe during fever, while in the same interval the mouth temperature rose 3 degrees, would be said to have a vasomotor index of 4. A high vasomotor index is interpreted as indicating a considerable element of vascular spasm and favoring operation, while low values indicate advanced occlusive disease in which operation is contraindicated.

METHOD OF CHOICE

The best method consists in the observation of the changes that follow the selective injection of sympathetic ganglions with procaine hydrochloride. In applying this method accurate measurements of the skin temperature of the involved extremity are taken with a thermocouple. Then an injection of procaine solution

is made in the region of the ganglions that are suspected of conducting the impulses responsible for the vascular spasm. An accurate injection should produce a temporary block which simulates the effect that may be expected from surgical extirpation of these ganglions. A rapid and marked rise in peripheral skin temperature indicates that spasm has been present and shows that the vessels are capable of dilatation. In the presence of advanced obliterative lesions in which there is relatively little hypertonus of vessels the rise is slight and slow in making itself evident. This method not only gives reliable information as to the condition of the vessels but indicates the exact point for surgical attack.

In cases in which pain is the major characteristic it is possible to differentiate visceral pain from somatic pain by this method of direct injection. Relief from pain following injection is a definite indication that the surgical interruption of these pathways will afford lasting relief. Failure to relieve the pain indicates either that the injection was improperly made or that the pain impulses do not follow these sympathetic pathways.

In cases of chronic arthritis I have found this method of great value. The accompanying charts represent the skin temperature curves of certain of these cases after injection with procaine hydrochloride. In each instance in which ganglionectomy was later performed the skin temperature of the side that was operated on has

Chart 3.—Skin temperature after injection with procaine hydrochloride in Mr. J. with endarteritis obliterans, right toe (indicated by solid line) involved; constant temperature reading, 30 C; needle reading, —6.

remained permanently elevated, closely approximating the maximum rise obtained during the preoperative test. In contrast charts indicating a great deal of vascular spasm a final chart is presented to show the slow and limited rise in temperature that results from injection in a case of advanced endarteritis obliterans. Any such curve as this contraindicates operation.

SUMMARY

An attempt has been made to classify the varied group of clinical syndromes for which sympathetic ganglionectomy has been advocated. On the basis of previous work, it is contended that pain impulses may arise from abnormal changes in tonus of peripheral blood vessels and it is suggested that spasm of the smooth muscle of vessels may account for many of the diseases classed in the group of visceral pain syndromes. The group of gastro-intestinal disturbances may be explained as due to hypertonus of sphincter muscle and for the third group it has been suggested that there is a common characteristic of functional limitation in blood supply. It seems probable, therefore, that smooth muscle hypertonus or spasm is a common characteristic of all the syndromes under discussion. Such a concept furnishes a working hypothesis which conforms with our present physiologic knowledge and affords a rational explanation for the beneficial results obtained by sympathetomy.

⁸ Buerger, Leo. Oscillometry in Nelson's Living Surgery, 4: 270.
⁹ Adson, A. W. The Surgical Indications for Sympathetic Ganglionectomy and Trunk Re-education in the Treatment of Diseases Resulting from Vasomotor Spasm of Peripheral Arteries. Bull. New York Acad. Med. 6: 17 (Jan. 25) 1910. Adson, A. W. and Brown, C. F. Thoracic and Lumbar Ganglionectomy in Peripheral Vascular Disease. J. A. M. A. 94: 230 (Jan. 25) 1930. Physiological Effects of Thoracic and of Lumbar Sympathetic Ganglionectomy or Section of the Trunk Arch. Neurol. & Psychiat. 22: 323 (Aug.) 1929.

The best method for obtaining a reasonably accurate estimate of the benefit that may be expected to follow sympathectomy consists in the selective injection of ganglions with procaine hydrochloride. The method is not particularly dangerous or difficult, and it accurately reduplicates for a short period the condition that may be expected to obtain more permanently after surgical excision of particular ganglions. It affords a method for differentiating somatic from visceral pain and, of more importance, should prove of great value in enlarging the field for the application of this new type of surgery.

THE INDISPENSABLE USES OF NARCOTICS INTRODUCTION

MORRIS FISHBEIN, M.D.
CHICAGO

For many years, physicians have had to meet the charge that they were responsible to a considerable extent for cases of drug addiction through the unnecessary prescribing of narcotics, through the prescribing of narcotics over a long period of time when a short period would have sufficed through the prescribing of proprietary remedies containing narcotic drugs without appreciating the presence or amount of narcotic drugs present, through failure to use substitutes for narcotics on some occasions, and, indeed even for having consciously prescribed narcotics for those addicted and who might have been controlled in some other manner. Obviously physicians must take responsibility for some drug addiction. These articles are planned to diminish as far as possible the cases for which physicians may be blamed.

One of the chief difficulties in the control of drug addiction is the absence of actual knowledge concerning the number of drug addicts, the causes of drug addiction and the methods of its promotion. There seems to be no doubt that the vigorous enforcement of the Harrison Narcotic Act has resulted in a lessening of narcotic addiction. It is the opinion of the Commissioner of Narcotics, who is responsible for narcotic law enforcement, that the control of legal importation, manufacture and distribution seems to be reasonably effectual. He says, furthermore, that the quantity of narcotic drugs of domestic manufacture that is diverted to illicit use is so comparatively negligible as to give no cause for alarm.

Dr W. L. Treadway of the U. S. Public Health Service is convinced that the first factor in drug addiction is ease of access to the drug. From the experience of the Division of Mental Hygiene of the Public Health Service, Dr Treadway believes that the immediate or precipitating causes of addiction may be for convenience or divided into first previous use of drugs in medical treatment second self-treatment for relief of pain, third, recourse during emotional distress fourth, influence of other addicts both in the community and in prison, and fifth indulgence for the sake of curiosity, thrill, or bravado. Among 1,225 addicts where the cause for addiction was known 23 per cent were due to previous

use of drugs in medical treatment, 17 per cent to self treatment for relief of pain, and 52 per cent to the remaining three causes that have been mentioned.

Addiction is more readily induced in some persons than in others. "The most important predisposing cause," says Dr Treadway, "is an inherent mental or nervous instability. On the one hand there is the normal individual, on the other the frank or gross mental disorders, and in between a large group who have been designated as a temperamental type, but who are in reality suffering from the psychoneuroses or dementia praecox type of disorder. Evidence is at hand, however, to show that addiction may be induced by the injudicious use of drugs in persons apparently free from any nervous or mental instability, and conversely, that due care in administration may avert this result even in the unstable."

The report of the Advisory Committee in Traffic in Opium and Other Dangerous Drugs of the League of Nations, published in November, 1930, indicates that only a small proportion of the narcotic drugs manufactured in the United States is clandestinely used for nonmedical purposes, and that considerable amounts of morphine, heroin and cocaine are being smuggled into the United States on the East coast and large quantities of prepared opium on the West coast. A careful consideration of the available reports and studies indicates that there are not more than a hundred thousand drug addicts in the United States at the present time. As an indication of the extent of such illegal traffic during the year July 1, 1927, to July 1, 1928, there were seized 3,718 pounds of opium, 5,048 ounces of morphine, 9,305 ounces of heroin and 1,122 ounces of cocaine. For the year ended June 30, 1930, there were seized 23,948 ounces of various narcotic drugs and preparations. It is thus apparent that the physicians are by no means responsible for all the narcotic addiction and that the problem is largely a police problem as well as a medical one. Notwithstanding this fact, it is the duty of every physician to limit the prescribing of narcotic drugs to cases in which the prescriptions are essential, and in which, after due thought, he is convinced that no other drug will suffice.

The problem in the United States is not more serious than in some other parts of the world. America, however, uses more narcotics for medicinal purposes than any other country. According to W. E. Dixon, America requires 245 mg of morphine per capita, Europe, 152 mg, Asia, 8 mg, and Africa, 24.5 mg. Professor Dixon suggests that it is possible that Americans are more sensitive to pain than people of other countries. An investigation of the number of women who required narcotics during childbirth shows America, 70 per cent, Great Britain, 50 per cent, Spain and Russia, 5 per cent.

All sorts of schemes have been suggested for controlling more certainly the manufacture and use of narcotics. The United States has a greater border to patrol than any other nation, so that the prevention of smuggling is much more difficult.

The problem of narcotic addiction merits the attention of physicians for many reasons. The control by statute of the prescribing of alcohol, and the definite limitations of the amount prescribed, indicates that the medical profession must do everything possible to minimize the prescribing of narcotics in order to make unnecessary further restrictive measures. Physicians should give more serious consideration to the materia medica, pharmacology and therapeutics of narcotics.

Physicians may, by the exercise of more thought in practicing, do much to avoid censure in relation to narcotic addiction. They may substitute, whenever possible, non-habit-forming drugs in the place of morphine or other opium alkaloids. When narcotics are indispensable, however, as shown in this series of articles, no more should be administered than is necessary to achieve the desired end. Patients requiring daily administration should be seen often by the doctor and the amount of drugs ordered or supplied should not exceed that required by the patient until seen again. Independence of administration on the part of nurses should be strictly limited to prescription and any change in treatment should be in writing.

The patients should never be informed of the nature of the drug used, nor of the dose of drug administered. The patient should never be permitted to administer the drug hypodermically to himself. Use of the drug should be discontinued immediately when no longer required, and if craving has resulted, close supervision and appropriate treatment should be maintained until the patient has been rendered independent of the drug.

The National Research Council is attempting to solve the problem in several ways. It is promoting research with a view to finding some synthetic preparation derived from opium which will have all the qualities of opium and narcotics without the tendency to establish addiction. Believing in the importance of proper education of the medical profession, the Committee on Drug Addiction of the Division of Medical Science of the National Research Council and the Division of Mental Hygiene of the United States Public Health Service in cooperation with the American Medical Association have arranged for the preparation and publication of a series of articles on the indispensable uses of narcotics. The expense of preparation has been met through an appropriation from the Bureau of Social Hygiene, Inc. This series, after its publication in *THE JOURNAL*, will be republished in book form. The articles to be published include the following contributions:

- The Indispensable Uses of Narcotics in Surgery Elliott C Cutler and John W. Holloway, Cleveland
- The Indispensable Uses of Narcotics in Medicine Frederick Tice, Chicago
- The Indispensable Uses of Narcotics in Obstetrics and Gynecology Joseph B. DeLee, Chicago
- The Therapeutic Uses of Narcotic Drugs Horatio C. Wood, Jr., Philadelphia
- The Indispensable Uses of Narcotics in Local Anesthesia Geza de Takats, Chicago
- The Indispensable Uses of Narcotics in the Practice of Otolaryngology Robert Sonnenschein, Chicago
- The Indispensable Uses of Narcotics in the Treatment of Coughing Robert A. Hatcher, New York
- The Indispensable Uses of Narcotics in the Treatment of Diseases of the Gastrointestinal Tract Robert A. Hatcher, New York
- Psychotherapy as a Substitute for Narcotics R. B. Richardson, Toronto, and T. H. Weisenburg, Philadelphia
- The Abuse of Narcotics Bernard Fantus, Chicago
- Narcotics in Proprietary Remedies Arthur J. Cramp, Chicago
- The Legal Aspects of the Use of Narcotics William C. Woodward, Chicago
- The Chemistry of Barbitol Substitutes for Narcotics Paul N. Leech, Chicago

The first of these articles appears in the current issue of *THE JOURNAL* and the remaining articles will follow.

THE INDISPENSABLE USES OF NARCOTICS

NARCOTICS IN SURGERY*

ELLIOTT C. CUTLER, M.D.

AND

JOHN W. HOLLOWAY, M.D.

CLEVELAND

The great debt of surgery to narcotics, and especially to those drugs which from time to time create such a desire for repeated amounts that they are referred to as habit forming, is acknowledged by all surgeons. Without narcotics there could not be surgery as we understand it, nor would there be anesthesia. Even without the habit-forming narcotics—cocaine, opium and their derivatives—the medical profession would find itself severely handicapped, for perhaps, above all, medicine is a merciful calling and, although it yields some specific cures, its chief reason for existence is the relief of suffering.

In order that the uses of habit-forming drugs in surgery may be clearly outlined, we have decided to divide our discussion into three parts: (1) the preoperative and diagnostic period, (2) the operation with its preparatory and recovery phases, and (3) the care of patients with inoperable disorders, including those cases of cancer in which surgery is inadvisable. In the third group we are eventually led to a discussion of euphoria and its place in a civilized community, a matter only touched on here, and perhaps better and more wisely left for another discussion.

THE PREOPERATIVE PERIOD

The preoperative period should properly be spoken of as the "study period." It is the time when a proper diagnosis should be made, and, although it may necessitate innumerable tests, the outstanding requirement is that the patient during this period be kept as uninfluenced by drugs as possible. Pain is one of the chief diagnostic signs, and if the diagnostician is robbed of its significance through the careless and often too free use of morphine and its derivatives, its aid is removed. Those who have seen patients with abdominal or intracranial disease rendered so comfortable and even drowsy that all complaints have disappeared know the danger of the premature use of drugs. However, if the investigative period is indicated for the clarification of the diagnosis, it should be carried out as expeditiously as possible, for to subject a patient to continuous pain over any great period of time is a decided reflection on one's diagnostic acumen. In the excruciating pain of smooth muscle colic, as seen in patients with renal and biliary calculus, the use of morphine would seem to find full justification. In this group of disorders, however, the administration of atropine and the application of heat may prove efficacious, and this therapy deserves wider usage.

It is in the field of traumatic surgery that morphine again assumes an important role and because of its

* From the Department of Surgery, the Leland Hospital and the Western Reserve University School of Medicine.

The articles are prepared under a plan of cooperation between the American Medical Association, the Committee on Drug Addiction of the Division of Medical Sciences of the National Research Council, and the Division of Mental Hygiene of the United States Public Health Service. Their object is to reduce the legitimate use of addiction drugs to a minimum by replacement, wherever possible, with other remedies that will accomplish the desired result. The physicians of the United States are the essential group in any such attempt and it is hoped that the articles will be useful to them in their practice. The funds for this work have been donated to the National Research Council by the Bureau of Social Hygiene, Inc.

ready availability, ease of administration and relatively certain and rapid action, it is almost indispensable. Here the likelihood of the manifestation of its one objectionable feature is reduced to a minimum. To those who went through the war as surgeons, particularly to those who worked nearest "the line," it almost seemed that military surgery would have been impossible without morphine. In cases of severe trauma the drug not only brings the necessary relief from suffering but, it shock intervenes constitutes one of the chief therapeutic weapons. In such conditions it is our belief that morphine should be given promptly in sufficient dosage to avoid frequent repetition. The healthy adult requires morphine, 0.015 Gm, subcutaneously.

THE OPERATIVE PERIOD

It is unnecessary to emphasize the desirability of establishing such an attitude in the patient that he approaches the operative ordeal whether it is under local or general anesthesia with a complete lack of apprehension. Although this is the result to be sought after needless to say it is not always obtained. However morphine lends itself to this purpose about as readily and satisfactorily as any drug that is available at present. Possibly in the future a satisfactory substitute will be devised. As a matter of fact some of the recently modified barbitol derivatives and tribrom-ethanol prove very satisfactory as a preliminary to anesthesia. Although definite progress has been made in this respect morphine, either alone or combined with other synergistic drugs, continues to be the most universally satisfactory type of preoperative medication. We desire, however, to emphasize our personal experience with tribrom-ethanol although this is not yet extensive. When this drug is used in doses of about 50 mg per kilogram, we have found that, except in cases of toxic goiter, the patient is brought to the operating room in a comfortable and almost sleepy condition. When this drug is followed by either procaine hydrochloride or nitrous oxide-oxygen anesthesia, a very satisfactory anesthesia results, although subject to the individual variation in response characteristic of all forms of alimentary medication. When larger amounts of tribrom-ethanol are employed and are supplemented by a general anesthetic, one occasionally finds that general anesthesia is sometimes induced with more difficulty because of the shallowness of the respiration. It would appear to be a particularly useful combination for patients with increased intracranial pressure for whom morphine is not only inadvisable but dangerous because of its depressant action on the already impaired medullary center. However, we recognize that one of the reputed untoward effects of tribrom-ethanol may be its action upon the respiratory center. We have found it useful for all intracranial procedures that can be carried out under local anesthesia including avulsion of the sensory root of the gasserian ganglion in cases of tic douloureux.

The matter of local anesthesia and the dangers of cocaine have been repeatedly discussed. One of us, who is a member of the Committee on Local Anesthesia of the American Medical Association, has unhappy recollections of the dangers that follow the use of cocaine. The studies¹ made by this committee have been concerned with the immediate mortality from

the use of this drug and not with the later misfortunes of addiction. It should be necessary only to repeat the conclusions of the committee that the injection of cocaine through a needle is, in the light of present knowledge concerning the effective substitutes for this drug, absolutely inexcusable. Unfortunately, science has not yet provided a substitute that will satisfactorily produce anesthesia when placed on the conjunctiva and mucous membrane, although in the former case holocaine is quite useful. Until such a drug is forthcoming ophthalmologists and otorhinolaryngologists must continue to use cocaine for producing anesthesia by application to surfaces. However such surgical specialists are not excused from the rule against injecting this drug and should know that the chief toll of life in recent years lies with those who inject cocaine for tonsillectomy.

After an operative ordeal it is of paramount importance to reduce the discomfort of the patient to a minimum, morphine should not be spared to accomplish this end, but it should not be employed indiscriminately. Frequently the patient's discomfort may be due to quite tangible conditions, such as position an unnecessarily tight dressing or urinary or intestinal distention these can be dealt with specifically rather than symptomatically by the injection of morphine, although to follow the former course necessarily involves slightly more effort on the part of those in attendance. In the first twenty-four to seventy-two hours following many major procedures the patient should receive sufficient morphine to keep him comfortable, provided an honest effort has been made to ascertain that his discomfort cannot be corrected by some simple remedial measure. Here again, no doubt, in certain instances, other sedatives may be substituted for morphine, but in general such substitutions, with the possible exception of codeine prove unsatisfactory. A further contraindication to large quantities of morphine after operation is that this drug might add a degree of atony to the intestines which might prove undesirable particularly if there was a preexisting tendency in this direction. However, one may with some justification construe distention to be an effort on the part of nature at immobilization of the bowels. This possibility may find its practical application in the Ochsner regimen advocated in the treatment of peritonitis, in which morphine almost assumes the role of a specific remedy. The adherents to this regimen are so numerous that one must conclude that the results have warranted their confidence in it. There are those who accept it as an excellent form of therapy but would modify it by returning morphine to the role of a symptomatic adjuvant, which would mean a marked diminution in the amount of morphine employed the therapeutic indication for its usage being the same as under any other circumstances. There can be no great objection to the use of morphine during a relatively brief postoperative period following which we are so optimistic as to believe that the patient will be relieved of his original complaint.

THE CARE OF PATIENTS WITH INTOLERABLE DISORDERS

Finally, we must consider the patient with an incurable and painful disorder. Many cases of cancer present this combination, long before death is imminent. Here again, as in trauma there can be no cavil with the use of morphine. Indeed, one can imagine that under these circumstances the fantasy, isolation and satisfac-

1. Mayer, Emil. The Toxic Effects Following the Use of Local Anesthetics. J. A. M. A. 52: 876 (March 15) 1923. An Analysis of the Reports of Fatalities Following the Use of Local Anesthetics with a Summary of Recent Studies on the Subject Including a Summary of Fourteen Additional Fatalities not Hitherto Recorded. Ann. Otol. Rhin. Laryng. 32: 404 (March) 1923.

tion of the morphine habit might be a just and desirable condition. Thus, when an incurable lesion becomes associated with great pain the patient can justly look to his physician for euthanasia. It is then the physician's responsibility not only to provide it but also to regulate it in order that the maximum relief over the greatest period of time may be obtained all of which requires no little cooperation between the patient and the physician. At the outset any one of a number of sedatives may prove somewhat useful, but ultimately in the majority of circumstances, morphine alone will meet the requirements, although there will be great individual variation. In certain instances rhizotomy or chordotomy may be employed very effectively for the alleviation of pain thus in some degree diminishing the necessity for the usage of large amounts of morphine.

One should also mention the other drugs heroin, codeine and ethylmorphine hydrochloride which have their devotees. Although ethylmorphine hydrochloride may have its uses in ophthalmology, we cannot as surgeons imagine conditions in which the prolonged use of these drugs, with the exception of codeine would be either justifiable or desirable. There are instances when codeine can be substituted for morphine quite effectively, and one should always consider this possibility, particularly in view of the almost complete absence in this drug of any tendency to the production of addiction. When administered by mouth it may be combined advantageously with some of the coal tar derivatives.

SUMMARY

Surgeons are concerned only with drug addiction due to cocaine and morphine. All the cases that we have seen, as well as much of the material published lead us to look on the "addict" as an individual with a perverted and degenerate personality, although obviously certain reservations must be made. Nevertheless our views are rather fatalistic about such personalities. Still it behooves surgeons to share in the general and desirable effort to keep habit forming drugs from such individuals. Cocaine needs no further comment. Its use is justified only in surface applications. As to morphine, we believe that from the standpoint of the surgeon it is the most valuable drug in the pharmacopeia, that it is essential in trauma and in certain very painful crises, that it should seldom be administered until a diagnosis can be made, and that in the preoperative and postoperative care of patients its use may be reduced by a proper study of substitutes.

Nephritis in Children.—Marriott stated that one of the most important and clearcut manifestations of infection in the nose and throat of children is tubular and glomerular nephritis. He also stated that nephritis is invariably associated with infection and most frequently with infection of the nose and throat. In practically all cases of nephrosis in children under his observation he found infection of the nasal sinuses particularly the antrums. *Staphylococcus hemolyticus* was found to be the most common infecting organism. He reported remarkable effects with treatment one patient losing 15 pounds (6.8 Kg.) of fluid following the drainage of an infected sinus. He has followed several cases for a number of years with no remaining evidence of nephrosis. In some cases however treatment brought about only temporary and symptomatic improvement because it was not always possible to eradicate the infection completely. He expressed the belief that infections of the nose and throat are likely to lead to permanent changes in the kidney and that the most to be expected is the prevention of further damage and progressive change. —Wimmer, S. D. The Relation of Sinusitis to Nephrosis in Children. *Irish Otol.* February 1931.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. LUCKEY, Secretary

IOPAX—Sodium 2-oxo-5-iodopyridine- λ -acetate—Sodium 5-iodo-2-pyridon- λ -acetate— $\text{CH}_3\text{O}^-\text{N}^+\text{CH}_2\text{COO}^-\text{Na}^+$. The sodium salt of a 2-oxo-5-iodopyridine- λ -acetic acid. Iopax contains from 42 to 43.5 per cent iodine.

Actions and Uses.—Iopax is proposed for use intravenously in radiographic visualization of the urinary tract. It is also used for injection into the renal pelvis through the ureteral catheter for pyelography. After injection the patient's face immediately becomes flushed and tachycardia and palpitation occur. Patients experience a feeling of general warmth, and in more than half of the cases they complain of pain in the arm near the shoulder which they describe as a feeling that the arm is bursting. There is usually considerable dryness of the throat and thirst but water is withheld in order that the drug may be secreted in concentrated form. These symptoms usually pass off within ten minutes. Occasionally nausea and vomiting take place and urticaria has been observed. Symptoms resembling acute iodism manifested by lacrimation, sneezing and dyspnea have occurred but such reactions have been transitory and delayed reactions have not been observed. After ten minutes from the onset of injection untoward symptoms have not developed.

Roentgenograms are taken from fifteen to twenty minutes after injection and again from thirty to forty minutes after the first roentgenogram. Before the second roentgenogram is taken the bladder is emptied in order that the shadow of the drug in the bladder will not obscure the lower parts of the ureters. If the first plates show that but little of the drug has been secreted it is presumed that the kidneys are functioning poorly and several hours should be allowed to elapse during which plates should be made at intervals. Impairment of renal function will allow but poor concentration of the drug in the bladder and practically none in the kidney; many hours are required for its secretion.

Dosage.—The maximum necessary dosage intravenously is 50 Gm. of the powder dissolved in 100 cc. of redistilled water for infants and children from 20 to 100 cc. according to age. The solution warmed to body heat is injected slowly into the cubital vein.

Manufactured by Schering-Kahlbaum A. C. Berlin, Germany (Schering Corporation New York distributor). U. S. patent applied for. N. C. trademark.

Iopax occurs as a lemon-yellow crystalline powder possessing a slight pungent odor and a characteristic taste very soluble in water. An aqueous solution is neutral to litmus.

Fuse about 0.2 Gm. of iopax with 2 Gm. of powdered sodium hydroxide; it decomposes with evolution of both iodine vapors and ammonia. Dissolve about 0.5 Gm. of iopax in 100 cc. of water add an excess of diluted hydrochloric acid; collect the resultant 2-oxo-5-iodopyridine- λ -acetic acid on a filter wash and dry in a partially exhausted desiccator; it melts at 230°C. to 1 cc. of the foregoing filtrate add 10 cc. of uranyl zinc acetate solution a yellow precipitate results. Transfer about 0.5 Gm. of iopax to a glass stoppered cylinder add 25 cc. of a diluted nitric acid; shake for five minutes; filter; the filtrate yields no distinct turbidity on the addition of 2 cc. silver nitrate solution (absence of inorganic halides). Dissolve about 0.5 Gm. of iopax in 50 cc. of water add 1 cc. of diluted hydrochloric acid; filter; separate portions of 10 cc. each of the filtrate add no turbidity on the addition of 1 cc. of barium chloride solution (sulphate); no coloration or precipitation on saturation with hydrous sulphide (salts of lead and metals).

Dissolve about 1 Gm. of iopax accurately weighed to constant weight at 100°C. the loss in weight does not exceed 1 per cent. Transfer about 0.5 Gm. of iopax accurately weighed to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the official method in the Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, second edition, page 48, the percentage of nitrogen corresponds to not less than 4.5 per cent nitrogen or than 4.8 per cent when calculated on the dried substance. Weigh accurately about 0.5 Gm. of iopax in a tared platinum dish add 10 cc. of dilute hydrochloric acid gently heat while fumes of chlorine and hydrochloric acid are evolved repeat using two portions of 2 cc. of dilute hydrochloric acid respectively ignite and weigh as sodium chloride; the weight found corresponds to the theoretical percentage of sodium chloride. For the purpose of calculation the dried substance contains 0.11 Gm. of iopax as a basis for determining the percentage of iopax. Carus method the amount of iodine found in the dried substance is 42 per cent of the theoretical amount.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS

W. A. PUCKNER, Secretary

BOVININE AND NEOBOVININE NOT
ACCEPTABLE FOR N N R

Bovinine and Neobovinine are marketed by the Bovinine Company of New York and Chicago. In 1909 the Council reported that while Bovinine was advertised as a condensed beef juice prepared by a cold process, it was not meat juice but a mixture of alcohol glycerin added sodium chloride and apparently some form of defibrinated blood. The Council reported further that numerous misrepresentations appeared on the label and in the literature of Bovinine (*THE JOURNAL*, Nov. 20, 1909 p. 1745). In 1914 to determine whether the claims made for Bovinine had been revised to agree with the facts and also to determine whether certain criticisms of the previous report which had been made by the exploiters of Bovinine required a revision of its conclusions, a further examination of Bovinine was made by the Council (Reports Council on Pharmacy and Chemistry, 1914 p. 105). This examination demonstrated that the unwarranted and false claims previously objected to were for the greater part still made and also that the conclusions of the first report were fully warranted by the experimental evidence. The Council has not given consideration to the product since the report in 1914 was issued.

Attention having again been called to Bovinine through the advertising for a similar one, Neobovinine, which is marketed with it, a referee made an examination of the advertising with a view to determine whether either or both of the products remained open to the objections which the Council had previously published. The referee reported that for Bovinine the situation remained about the same as when the product was last considered. He found no reason for considering this preparation in any way acceptable. In the leaflet that advertises Bovinine and Neobovinine one encounters such unsupported statements as the following: "It will assist in making up for the wear and tear of metabolism without an excessive burden for absorption." "BOVININE (*Plan*) exerts a stimulatory action on general metabolism, causes a definite improvement in appetite and allows a higher caloric intake with a resulting effect on hemoglobin production." "BOVININE (*Plan*) is a preparation of fresh beef blood. It contains proteins complements and nutrients so necessary to general metabolism." "BOVININE (*Plan*) ranks high in alkaline reaction and is therefore a suitable all round food in acid conditions or peptic ulcer." "Clinical evidence comes to us that in Pernicious Anemia by combining BOVININE (*Plan*) with liver extract the results may be more rapid and the dosage of liver extract reduced."

Neobovinine 20 is stated to be "essentially BOVININE (*Plan*) in which is incorporated the active principle of fresh whole liver." Certainly the combination of Bovinine with a liver extract of undeclared character must be held an unscientific mixture. The case histories are entirely unsatisfactory and report conditions in which it is known that there could not possibly be the results reported, such as purpura hemorrhagica and myelogenous leukemia. The cases of pernicious anemia are not reported with sufficient data on which to base an opinion.

The Council reaffirmed the rejection of Bovinine and declared Neobovinine unacceptable because the information in regard to its composition is inadequate because the therapeutic claims advanced for it are unwarranted and because the combination of "Bovinine" with a liver extract of undeclared character is unscientific.

"SPIN-L-RON" NOT ACCEPTABLE
FOR N N R.

"Spin L-Ron" is the nondescriptive name under which the Ford Pharmacal Company markets capsules each stated to contain spinach dehydrated 5 grains, liver extract powder 2 grains and iron and ammonium citrate, 3 grains. It is stated that the spinach content of each capsule represents 100 grains of fresh herb and that the liver extract represents 40 grains of fresh liver. The method whereby the liver extract is prepared is not declared although it is known that the action of liver

extracts depends on the process by which they are prepared. The advertising argues for the use of this mixture on the premise that "SPINACH is recognized as the richest Iron and Vitamin bearer of all plants", that liver extract 'has demonstrated its value in building up the blood and supplying its necessary tone and color', that it is being used today by leading specialists and clinics in pernicious anemia and that iron and ammonium citrate is "the most valuable of Iron salts." No reason is advanced for the use of spinach in capsule form rather than taking a mouthful of cooked spinach at meal. Nothing is said about the fact that the therapeutic action of liver extract depends on the method of its preparation and that the efficacy of certain liver extracts in pernicious anemia has little bearing on the use of liver in other conditions. As for the claim that iron and ammonium citrate is the most valuable of iron salts in anemic conditions, this is without warrant other iron salts are equally efficient and acceptable. No reasons are advanced why these three substances should be administered in admixture. According to the advertising Spin L-Ron "will appeal to the pale anemic apprehensive patient, toning up the whole system, bringing back strength and healthy glow by producing the necessary blood ingredients and improving appetite and digestion." This is a suggestion to physicians to prescribe this complex mixture to "pale, anemic, apprehensive patients" rather than diagnose and intelligently treat a patient.

The Council declared Spin L-Ron unacceptable for New and Nonofficial Remedies because it is a complex unscientific mixture of indefinite composition which is marketed under a nondescriptive name and with unwarranted therapeutic claim.

THYMOPHYSIN NOT ACCEPTABLE
FOR N N R

Thymophysin is said to be a preparation of posterior pituitary and thymus is manufactured by Fritz-Pezoldt of Vienna and is marketed in this country by the American Bio-Chemical Laboratories Inc. of New York City. The product is recommended as a reliable and safe means of accelerating delivery obviating the use of forceps in 75 per cent of the cases in which it is used. It is said to be absolutely harmless to mother and child and it is claimed that no harmful effects to either have ever been observed by its use. The special claim for this preparation is that the contractions of the uterus which follow its use are rhythmic in character rather than maintained, as is said to be the case following the use of pituitary alone.

Pharmacologic studies of this preparation or of thymus and pituitary mixtures are few, but most of the recent literature of a clinical nature refers to the paper by Temesvary, which appeared in 1926. Reference to this paper shows however, that it is concerned almost exclusively with the action of thymus extract and that there are only two tracings which have any relation to the modification of pituitary action by thymus. A comparison of these two tracings shows that whether the contraction pictured is produced by pituitary alone or by pituitary plus thymus there is no essential difference between them. Similar slight differences are always to be found when successive doses of pituitary extract are given in the routine testing of the drug. This slender bit of so called evidence is the only pharmacologic study which appears to have been published to serve as a basis for the claims which are made for the product.

An extensive clinical literature has appeared since the date of Temesvary's paper, and in general these papers have reported favorable results from the use of the product. However, on account of the difficulties inherent in the situation such clinical reports cannot be accorded too great weight. It would be extremely difficult to distinguish slight degrees of differences in the length of the individual contractions of a uterus in labor. The drawing of such false deductions is well illustrated by those forming the basis of the recent popularity of watery extracts of ergot for hypodermic injection which investigations have shown to be lacking in the essential alkaloids of ergot. This made it necessary that Thymophysin be subjected to examination by accurate pharmacologic methods to see whether the claims made for it are justified or whether it might not be merely a weak pituitary extract which, because of the presence of this substance, could shorten labor but which also because of

its relative weakness, might be safer to mother and child than would pituitary extract alone as it is only too frequently given. Such a study, therefore, has been made by Prof. Erwin C. Nelson of the Department of Pharmacology of the University of Michigan. His paper appears in *THE JOURNAL*, January 31, page 352. After a critical survey of the literature, Nelson studies the action of Thymophysin itself in comparison with pituitary and again the action of thymus in connection with pituitary. Full details of these studies appear in the paper.

The conclusions drawn by Nelson in his excellent paper are that there is no unequivocal evidence that either oxytocic or pressor activities of pituitary are altered by the simultaneous administration of thymus that experimentally no difference could be found in the oxytocic or pressor activities of pituitary alone as compared with pituitary plus thymus (in comparisons of Thymophysin with equivalent doses of pituitary no differences could be demonstrated). Finally, accurate assay of Thymophysin showed that the ampules contained only about 30 per cent of the strength claimed on the label. The lack of complete harmlessness has already been shown by reports which are appearing from time to time in the literature reporting rupture of the uterus, tetanic contractions and cervical tears following its use. In view of these reports the Council declared Thymophysin unacceptable for inclusion in New and Nonofficial Remedies since it is an unscientific preparation marketed under false claims as to its essential action, as to its strength and as to its safety for mother and child.

COMMITTEE ON FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COMMITTEE ON FOODS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIC, Secretary

LAND O'LAKE'S SWEET CREAM BUTTER

Manufacturer—Land O'Lakes Creameries, Inc., Minneapolis.

Description—A packaged salted or unsalted butter graded by official federal-state butter graders as rating 93 score or higher.

Manufacture—The cream used in the manufacture of this butter the conditions equipment and process of manufacture and the final product must meet certain published standards and requirements adopted by the corporation.

Cream deliveries from tuberculin tested cows are received four times a week in summer and three times a week in winter. Accepted cream contains not more than 0.20 per cent acidity as lactic acid and is clean and sweet of flavor. No neutralizer is used. The cream is pasteurized by holding at 155-158 °F. for thirty minutes and immediately cooled to 40 °F. No starter is added either before or after churning of the salted butter. A churning report is made for each batch. The butter is tubbed and sent to the central plant for grading and packaging. Unsalted butter is made by the same procedure as salted butter, but with omission of the salt.

A strict control is exercised over the processes and sanitation of the various creameries. Yeast and mold counts of the butter batches are made at intervals.

Before packaging the butter is graded according to government standards by federal state butter graders appointed by the U. S. Department of Agriculture in cooperation with the Minnesota State Department of Agriculture. The reports on each creamery batch include acidity of the cream before churning, the temperature of processing, composition of the butter, the method of manufacture and yeast and mold counts. The butter is scored on the basis of:

- 45 points on flavor
- 25 points on body
- 15 points on color
- 10 points on salt
- 5 points on package

A 'certificate of quality' issued by authority of the U. S. Department of Agriculture and declaring the score is placed

in each package. The Land O'Lakes Sweet Cream Butter scores 93 or higher."

Chemical Composition—

(proximate analysis)		Per Cent
Salt butter		
Moisture		15.8
Milk fat		80.7
Curd		1.0
Salt		2.5
Unsalted butter		
Moisture		16.0
Milk fat		83.0
Curd		1.0

Calories—

730	per gram
2073	per ounce
3317	per pound

Claims of Manufacturer—A delicious pasteurized sweet cream butter scoring 93 or better by butter graders of the U. S. Department of Agriculture and Minnesota Department of Agriculture. It is made from sweet cream and therefore has a different flavor from that of butter made of sour cream. This butter, always uniform, is one of the finest of butters.

KNOX PLAIN SPARKLING GELATINE (No. 1)

Manufacturer—Charles B. Knox Gelatine Company, Inc., Johnstown, N. Y.

Description—An unflavored unsweetened granular gelatin.

Manufacture—The mineral matter of crushed bones is extracted with dilute hydrochloric acid. The remaining organic matter is washed with water. Osseomucoids and other protein impurities are removed by treatment with suspensions of calcium hydroxide. Five fresh baths are employed in the course of from thirty six to forty days. The resultant collagen is washed with water until approximately free from soluble calcium compounds. It is adjusted to a pH of 6.5 with phosphoric acid and is pumped to cooking pans.

The collagen is converted to gelatin in the pans by hydrolysis with water at from 150 to 170 °F. The first extraction is made at 150 °F. and the third (final) at 170 °F. The gelatin solutions are filtered, concentrated under partial vacuum to from 13 to 15 per cent concentration, filtered, cooled, set to sheets of stiff jelly, placed on nickel drying frames, dried by warm filtered air in long chambers and ground to pass a 20 mesh screen. The granulated gelatin is packed in envelopes in cartons.

Knox gelatin is not chemically bleached nor does it contain preservatives. Strict sanitary control is exercised in the manufacture. The product is machine handled only. The plant equipment is largely aluminum, nickel or stainless steel. Control laboratories assure a uniform product.

Chemical Composition—

(proximate analysis)		
Moisture		13.0-14.0%
Ash		1.0-1.2%
Protein (N x 5.55)		85.0-86.0%
Fat (ether extract)		0.1%
Carbohydrates		0.0%
Arsenic as As ₂ O ₃	0.6 part	per million
Lead as Pb	0.0 part	per million
Copper as Cu	2.5 parts	per million
Antimony as Sb	0.0 part	per million
Zinc as Zn	0.0 part	per million
Sulphur dioxide	0.0 part	per million

Calories—

345	per gram
980	per ounce
1568	per pound

Claims of Manufacturer—Knox Sparkling Gelatine is always of high quality. It can be used in a wide variety of delicious desserts, candies, salads and other recipes and makes fruit and vegetables taste better and go further.

This gelatin contains no added sugar or flavoring and consequently is valuable for many special diets. It is one of the most readily digested proteins.

KNOX SPARKLING GELATINE (No. 3)

Manufacturer—Charles B. Knox Gelatine Company, Inc., Johnstown, N. Y.

Description—This product is essentially the same as the Knox Plain Sparkling Gelatine No. 1. Each carton contains two envelopes of Knox Plain Gelatine and one envelope of fruit acid (citric acid). The citric acid is intended for admixture with the gelatin in various recipe preparations if so desired.

SATURDAY MARCH 14 1931

THE CONTROL OF NARCOTIC ADDICTION

Narcotic addiction one of the most sensational subjects that engages medical and social thought is again the focus of an extraordinary amount of attention directed from various points of view for diverse reasons. Through the efforts of numerous leagues for combating narcotic addiction meetings are being held, accompanied by much newspaper publicity and planned apparently to urge restrictions on the manufacture of narcotics and on their prescription sale and importation. Special committees appointed in various cities and states are urging the establishment of farms and homes for drug addicts; they support their contentions that these will solve the problem by more or less scientific surveys and data. Several bureaus of the United States government including the Division of Mental Hygiene in the United States Public Health Service are making available the results of their investigations. The Wickersham committee, having brought forth what it brought forth about alcohol is now in labor on drug addiction and crime. The National Research Council, as emphasized in an editorial elsewhere¹ in this issue is stimulating research, leading possibly to the development of a narcotic that will have the potency of morphine without its propensity of inducing addiction. The Hearst press publishes editorials calling on the medical profession "to drive out the dope doctors" and stimulates the sale of newspapers by the syndication of the autobiography of a motion picture actress whose addiction and associated difficulties have been the subject of newspaper comment for several years. Such a mass attack must inevitably yield an appreciable result.

Several phases of the attempt to solve the problem of narcotic addiction are reflected in this issue of THE JOURNAL. The articles by Light² and by Lambert³ make available the results of studies carried on in the

narcotic wards of the Philadelphia General Hospital and of investigations by the Mayor's Committee on Drug Addiction in New York City. In these reports, many points of significance are emphasized. The taking of narcotics is usually an attempt on the part of someone with little will power to achieve a state of euphoria or artificial happiness. Once 'hooked' by the drug the addict finds withdrawal accompanied by exceedingly unpleasant symptoms. He tends to succumb again to his addiction through inability to withstand the thought of withdrawal or through repetition of the psychological situation that led to addiction. The significant point emphasized by Light and his associates is their belief that addicts will and can control to a large degree the intensity of their withdrawal symptoms and the opinion that such symptoms are so frequently complicated by nervous manifestations of the nature of hysteria that the control of narcotic addiction demands both psychiatric and psychological investigations of the persons affected. The work carried on in New York fully supports the Philadelphia results and adds thereto exceedingly interesting observations relative to the therapeutics of the withdrawal stage. Apparently it is possible for an experienced physician to carry an addict through the withdrawal period with relatively little distress provided the addict is under controllable conditions.

Another important feature of the current issue is the beginning of a series of articles concerned with 'The Indispensable Uses of Narcotics.' Described by Sir William Osler as 'God's own medicine,' the importance of narcotic preparations should not be underestimated. Nevertheless there exist in medicine innumerable occasions when one or more of the vast armamentarium of non-habit-forming sedatives, narcotics, hypnotics and analgesics singly or in combination may be employed to substitute for an opium derivative. It is the purpose of this series of articles to indicate to the medical profession the relatively few instances demanding the administration of opium or cocaine derivatives and the many substitutes therefor that may be available. Something under 25 per cent of narcotic addiction, it is estimated results from the beginning of the habit through previous use of drugs in medical treatment. This is after all only an estimate based largely on evidence derived from the addicts themselves, who are notoriously an unsafe source of evidence. Nevertheless the physician must strive to limit his prescribing of narcotics absolutely to those situations in which the narcotic may be considered indispensable. Thus he will avoid the possibility of unfavorable criticism.

Figures assembled by the League of Nations and by many other authorities indicate that the medical use of narcotics in the United States far surpasses that of

¹ Research for a Non-Habit-Forming Substitute for Morphine this issue p. 863.

² Light A. B. Physiologic Aspects of Opium Addiction this issue p. 823.

³ Lambert Alexander. Treatment of Drug Addiction this issue p. 825.

any other nation. The suggestion has been made in extenuation that the speed of modern life in this country is responsible and that the nervous system of the American is somewhat more sensitive than that of the inhabitant of other countries. However, others have insisted that the American physician is too easily inclined to the prescribing of narcotic drugs. Regardless of the validity of the evidence in support of these contentions, it is reasonable to ask that physicians attempt to restrict their prescribing of narcotics. Such restriction may help to determine whether or not the need which creates this large discrepancy in American prescribing is compared with that abroad is an actual or indispensable need.

The assertion has been made by the sensationalists that a great proportion of physicians are drug addicts as compared with the rest of the population. They shriek that a considerable number of physicians are consciously engaged in the creation of addiction for personal gain, hence the call by the Hearst press to drive out the dope doctor. THE JOURNAL states confidently that no county medical society, no state medical society, nor the American Medical Association will retain in its membership any physician who is convicted of such utterly unethical action. These officially organized bodies need no call from Mr. Hearst to drive out the dope doctor. The removal of licensure or of the right to practice medicine is not the prerogative of the American Medical Association but distinctly within the purview of the state medical licensing boards. The trial and conviction of such miscreants is the duty of the regularly established investigating, prosecuting and judiciary bodies of this country. They may be assured of all the help that the American Medical Association can render in purging the medical profession of those who have any conscious part in the creation and maintenance of narcotic addiction. Their activities reflect unfavorably on a profession of high standing and it will not tolerate them in its midst.

In the preparation of the series of articles that begins in this issue of THE JOURNAL many official agencies have cooperated. The list of authors includes men chosen for their competence in the fields of which they write. The articles are published under the auspices of the Committee on Drug Addiction of the Division of Medical Science of the National Research Council, the Division of Mental Hygiene of the United States Public Health Service, the American Medical Association and the Bureau of Social Hygiene, Inc. After the articles were prepared they were submitted to members of the Council on Pharmacy and Chemistry of the American Medical Association and to representatives of the various cooperating agencies for editing and revision. When completed these articles will be available in book form for permanent reference by physicians who wish to cooperate in the praiseworthy effort to limit prescribing of narcotics to indispensable uses.

RESEARCH FOR A NON-HABIT-FORMING SUBSTITUTE FOR MORPHINE

The popularity of endocrine, vitamin and diverse synthetic medicinal products in recent years has tended to obscure the significance of active constituents derived from the plant kingdom. The greater number of dependable and useful substances of natural origin in the therapeutic armamentarium may be forgotten because of the emphasis placed on synthetic products offered by the chemical industry. If it had not been for leads obtained from natural products the synthetic therapeutic products might not have come into existence. Frequently the standard by which the usefulness of a synthetic product is determined depends on a natural product. For instance, the activity and suitability of synthetic products intended for local anesthesia is determined by comparison with cocaine, the alkaloid of coca leaves, a natural local anesthetic, which with its derivatives is not yet surpassed in general usefulness and efficiency by any synthetic product.

The subordination of interest in natural products is the outcome of recognized commercial possibilities of synthetic products rather than a limitation of opportunities for achievement along fundamental and practical lines. The sterility that has possessed this field is to be deplored. Today, exceedingly few chemists and pharmacists concern themselves with the isolation and analysis of medicinal plant constituents. Some manufacturers prepare and market the few constituents that appear indispensable but generally industry is indifferent to the investigation of new possibilities. Examples of rewarded efforts are nevertheless at hand. For instance, hardly any one would deny that the additional though belated efforts were not well spent on two of the oldest alkaloids, ephedrine and quinine, which have achieved prominence and value. A better understanding of cardiac therapy could scarcely have been achieved without the persistent studies of the natural glucosides of digitalis by Cloetta of Zurich and a few others, notably Jacobs of the Rockefeller Institute in this country. Nothing is more essential than pure and definite constituents for satisfactory pharmacologic and therapeutic studies. But if the desirability of work in this line should be doubted, one need only reflect on the chaotic state of knowledge of the actions of opium for some hundreds of years until the isolation of its chief active constituent, morphine, by the pharmacist Serturner in 1803. The effect of this signal achievement for progress in therapeutics is written in the scientific records on a whole series of alkaloids discovered since that time.

Although the active constituents of many important medicinal plants are known, there is still plenty of room and opportunity for effective and creative work. The chemistry of most of the most important constituents remains unsettled, notable among these being morphine. The chemical structure and synthesis of this indis-

insoluble alkaloid still remain in doubt. Therefore it is news of more than usual interest that the Committee on Drug Addiction of the National Research Council¹ announces a large collaborative research in alkaloidal chemistry by chemists and pharmacologists of this country. Apparently the present object of the committee is to prepare a non-habit-forming substitute for morphine that would yet possess the desirable actions of morphine. The ideal molecule, apparently some hybrid molecule, is to be built up out of the desirable features of the morphine and codeine molecules. The experiment will be watched with much interest from many sides. If it merely stimulates interest and work in the chemistry of alkaloids and other natural medicinal constituents, the effort will have been well repaid. Thorough investigation of the natural products is likely to prove more instructive and important for a selected materia medica than the multiplication of synthetics, which in many instances represent minor modifications of a single product.

BOTULISM AND DUCKS

Kalmbach,² ornithologist of the Biological Survey of the United States Department of Agriculture, assigned to the problem of the so-called western duck sickness, recently made observations that open a wide field for further study of botulism in birds, particularly ducks. Western duck sickness has affected migratory water fowl in marsh lands of western states. Shore birds, geese and ducks, especially of the pintail, mallard and teal species, are subject to the malady. Foci of the disease have been noted in the Bear River marshes and neighborhood in Utah, the Tulare Lake and Buena Vista Lake districts in California, Lake Malheur in Oregon, and other areas in Idaho, Texas, Dakota and Canada. Though a relatively small percentage of birds in an area are affected, it has been estimated that, up to 1927, fifteen million ducks had died.

The disease ordinarily occurs during the hot and dry weather of the summer and fall and is associated with low water, decomposing vegetation and high salt concentration. Although it usually occurs annually, increased severity obtains in some years. Finally, there is a decided cessation of the disease when heavy rains occur or even a lowering of the temperature without rain. In fact, recovery occurs after two to four days in from 70 to 90 per cent of the affected birds, provided fresh water and food are supplied.

Heretofore, the popular theory has been that alkaline waters are the causative agent. Shaw,³ in a series of experiments, indicated that salt mixtures, particularly those containing nitrates, especially with nitrites, produced symptoms closely resembling those observed in the animals in the field. Moreover, postmortem appear-

ances are similar. In fact, this author reported that a nitrate soil extract of high toxicity of which 100 cc. of water extract was fed over a seven day period caused death. This observation may be of importance in the light of the recent evidence submitted. Kalmbach, however, used body tissue, particularly blood and liver, of animal dead of the disease. After incubation at 85 F for five or more days this was fed to normal animals in amount of 0.5 Gm. Death with symptoms resembling the disease ensued, while from 0.1 to 0.05 Gm allowed recovery. Of great interest was the observation that boiling for five minutes at an altitude of 4,137 feet destroyed the toxic material but that an extract of a toxic liver, filtered and injected into the abdominal cavity, produced typical results.

Apparently the results of Giltner and Couch,⁴ who isolated *Bacillus botulinus*, type C, from the mud of one area of duck sickness, indicate that western duck sickness may be botulism. This view is further strengthened by the independent studies of Hobmaier from the Hooper Foundation of the University of California.

Epidemiologically, several theoretical assumptions arise. Botulism, whether in birds or in man, is regarded as a true intoxication. The experimental data as to infection from the spore of *Bacillus botulinus*, a widely distributed soil organism, deserve more than passing notice from epidemiologists despite the fact that the preponderance of evidence indicates that human cases of botulism are caused by consuming food in which the toxin has been preformed. Before the hypothesis that duck sickness is botulism is accepted as proved, toxin of a suitable type must be demonstrated in the mud or the feed, or the infectivity of type C botulinus isolated from the mud must be experimentally proved. There is no doubt that *B. botulinus* grows best and produces a toxin of maximum potency in liver mediums. The feeding experiments with incubated liver of dead animals may be explained by contamination or incidental appearance in the liver of a soil anaerobe. Geiger,⁵ years ago, demonstrated that a toxin could be produced in "cased" home-made sausages, when contaminated under actual field conditions of preparation, but only on incubation at 37 C for seventy-two hours. The temperature growth curve of *B. botulinus* may well be within prevailing weather conditions, assisted by decomposing organic matter, its oxygen requirements may be met by the symbiotic interaction of aerobes and anaerobes. Furthermore, these duck areas must be heavily contaminated with fecal material and it is not unusual to isolate *B. botulinus* from such soils. Theiler and his associates⁶ reported the isolation of a botulinus-like organism from the toxic carrion

material that produced lamziekte, a fatal disease in cattle in Bichuanaland, Orange Free State, and in the northwest portion of Cape Province. According to Meyer and Gunnison, this organism resembled *B. botulinus*, type C, but only culturally, toxicologically it was a different and distinct type.⁸

Presumably, animal botulism may have respective types that are specifically toxic within certain limits and these may differ in different countries. What their relationship is to the disease as in these observations is at present obscure. We must, perforce, recall the report of the California Botulism Commission⁹ and perhaps remain in accord with its epidemiologic conclusion, that it must be shown that the preformed toxin and not merely the bacillus was present in the suspected food or the tissues of the diseased animals.

OXIDATIVE NATURE OF NERVOUS IMPULSE

A nerve deprived of oxygen rapidly loses its power to conduct the nervous impulse but soon regains it if oxygen is again supplied. It has been proved also that a nerve uses oxygen and gives off carbon dioxide during the passage of the nervous impulse and that this reaction liberates heat, which has been measured. Yet this does not prove necessarily that conduction of the nervous impulse is of an oxidative character, as waste products may be formed by the conduction, and these inhibit the process unless they are removed by oxygen.

After a nerve has been placed in an atmosphere of pure nitrogen, and oxygen is again admitted to the nerve chamber, there is an increased consumption of oxygen over the normal resting level, the increase being greater if the nerve is stimulated to activity during its stay in nitrogen. This demonstrates that a nerve is able to go into oxygen debt in the absence of oxygen, the debt being paid off when there is a supply of oxygen available. Under similar conditions, Schmitt¹⁰ has shown that extra carbon dioxide is not given off when a nerve is stimulated in nitrogen. Hence he assumed that conduction under anaerobic conditions may depend on the union of oxygen with some substance in the nerve, not necessarily a complete oxidation when the substance is oxidized to carbon dioxide. The only way that the nerve could obtain oxygen under anaerobic conditions would be from a molecule containing oxygen that was able to give up this oxygen readily when needed and later take up oxygen when it is again supplied to the nerve.

For several years Warburg¹¹ has been studying the iron-containing respiratory ferments in tissues having

the property of taking up molecular oxygen and of converting the oxygen into an active form that can be readily used by the tissues. Warburg has found that this reaction can be inhibited by carbon monoxide and he believes that the carbon monoxide combines with the respiratory ferment in a manner similar to the combination of carbon monoxide with hemoglobin. If a tissue is placed in an atmosphere of carbon monoxide and oxygen, the respiratory ferment will combine with these gases in proportion to their partial pressures, so that, if the amount of carbon monoxide is increased and the oxygen decreased, practically all the respiratory ferment will combine with the carbon monoxide. Under these conditions, respiration will cease as the supply of oxygen activated by the ferment decreases.

Haldane showed that the ratio of hemoglobin combined with carbon monoxide to hemoglobin combined with oxygen can be altered by the action of light, which has the property of splitting up the carbon monoxide-hemoglobin compound into carbon monoxide and hemoglobin thus diminishing this compound and increasing the amount of hemoglobin available for combination with oxygen. A similar reaction occurs with Warburg's respiratory ferment. Respiration of isolated cells may be decreased if carbon monoxide is added to the gases in the cell chamber in the dark, the carbon monoxide combines with the respiratory ferment. This inhibition of respiration will disappear when light is thrown on the cell suspension. Light causes the carbon monoxide combined with respiratory ferment to be replaced by oxygen and respiration may proceed as the ferment again activates oxygen.

A similar mechanism of oxidation takes place in the nerve. Schmitt¹² tested the effect of mixtures of carbon monoxide and oxygen on resting nerves and found that respiration is decreased in carbon monoxide in the dark but that, if the nerve chamber is illuminated, the usage of oxygen will be increased, similar to the change in respiration found by Warburg on cell suspensions. To corroborate this observation, Schmitt studied the effect of mixtures of carbon monoxide and oxygen on the action potentials of nerves. He found that the intensity of the action potential of a nerve can be reduced to zero in a mixture of carbon monoxide and oxygen and in darkness but that if light is thrown on the nerve the action potentials will be restored to normal. If the nerve is placed in nitrogen and in darkness, the action potentials can be reduced to zero but cannot be restored by the action of light thus showing that light has a specific effect on the respiratory ferment and not a general effect on the nerve.

From these experiments Schmitt concludes that the action potentials in the nerve are primarily of an oxidative nature and that the oxygen used in the process requires activation by the respiratory ferment which

may be poisoned by carbon monoxide. It would seem plausible that the ferment simply provides the source of activated oxygen.

These experiments are interesting for the new clues which they provide with regard to the actual mechanisms that are involved in nerve conduction. They show, furthermore, a correlation between the oxidative processes in various types of cells.

Current Comment

AUTOMATIC ENVIRONMENTAL VACCINATION

Native proteins are generally described as nondialyzable. This definition is so firmly established in biochemistry that the mere demonstration of dialyzability is accepted as proof of nonprotein nature. The gastro-intestinal mucosa is a colloidal membrane. It follows, therefore, that an undigested native protein cannot normally pass from the gastro-intestinal contents into the blood stream, any observed passage being proof of local abrasions or destructive lesions. These conclusions are firmly entrenched in the theory and nomenclature of physiology and clinical medicine and have given rise to numerous puzzling paradoxes, particularly in the field of infectious diseases and immunity. Yet both conclusions are erroneous, if one is to credit the experimental evidence currently reported by Dr. A. F. Coca¹ of Cornell Medical College, New York, who for the first time has studied protein dialyzability by modern serologic techniques. Coca tested the dialyzability of egg white and of each individual egg protein, using carefully selected, pressure tested fish bladders, collodion sacs and parchment shells. The dialysates were first concentrated from 500 to 1,000 times by the electric fan, then titrated with specific rabbit precipitins, and tested for antigenic and allergic properties in guinea-pigs. Briefly, Coca reports that by the end of five days approximately 1 per cent of each individual egg protein had passed through his dialyzing membranes, an average hourly rate of about 1 part in 12,000, the area of the membrane not being given. This is equivalent to approximately 1 mg. of egg protein absorbed into the circulation by the end of the first fifteen minutes after swallowing a raw egg, assuming, of course, no increase in absorption surface and an identical permeability. The amount absorbed may well be a hundred times greater than this, because of the relatively huge gastro-intestinal surface. Apparently one must conclude from the Coca dialyzation coefficient that undigested food proteins are normally absorbed unchanged from the gastro-intestinal tract, with an ever increasing absorption at each stage of protein cleavage. This absorption may conceivably serve the useful purpose of constantly maintaining the human body in a state of immunization against habitual protein diets without which automatic environmental vaccination the first destructive lesion of the gastro-intestinal tract might be followed by explosive protein toxicity.

Association News

THE PHILADELPHIA SESSION

Clinical Lectures at Philadelphia

The program of clinical lectures presented herewith has been arranged by the Council on Scientific Assembly and will be given on Monday, June 8 and on Tuesday, June 9 at the annual session to be held in Philadelphia. The clinical lectures at the last several annual sessions constituted a distinct feature of each scientific program and in most instances have been splendidly attended. The topics to be discussed are of important, practical value to practicing physicians and the speakers selected by the Council are men of wide experience who have given serious study to the subjects they will discuss.

The Clinical Lecture Program will be given in the Irvine Auditorium of the University of Pennsylvania, which is only a short distance from the Municipal Auditorium where the Registration Bureau and all of the Association exhibits will be installed. Monday morning will be left free for registration so that no one will need to miss the clinical lectures that will begin at 2 p. m.

MONDAY AFTERNOON, JUNE 8

Blood Pictures in Anemias, Leukemias and Allied Disorders of Blood. CARLS C. STURGIS, Ann Arbor, Mich.
Treatment of Anemias. GEORGE R. MINOT, Boston.
Clinical Value of Blood Chemistry Determinations. ROBERT T. WOODWARD, Chicago.

TUESDAY MORNING, JUNE 9

Fungus Diseases. CHARLES MARIORY WILLIAMS, New York.
Variations in Methods of Treatment of Syphilis. PAUL A. OLFAND, Rochester, Minn.
Deficiency Disease. Clinical Recognition and Management. JOHN H. MUSSEL, New Orleans.

TUESDAY AFTERNOON, JUNE 9

Differential Diagnosis of Coma. HOWARD C. VERFZIGER, San Francisco.
Surgical Handling of Diabetic Patients. L. S. MCKITTICK, Boston.
Types and Treatment of Chronic Rheumatism. RUSSELL L. HADEN, Cleveland.

Scientific Exhibit Special Exhibit on Fractures Under Direction of Cooperative Committee on Fractures

The Cooperative Committee on Fractures, appointed by the Section on Surgery, General and Abdominal and the Section on Orthopedic Surgery, has been requested by the Committee on Scientific Exhibit to continue the exhibit for the Philadelphia Session. The Cooperative Committee on Fractures has acceded to this request.

Those who compose the committee are as heretofore: Drs. Nathaniel Allison, Chicago; William Darrach, New York; and Kellogg Speed, Chicago. This committee announces as members of its Advisory Committee: Drs. W. S. Bier, Wallace Cole, F. J. Cotton, R. B. Dillehunt, E. L. Elason, George W. Hawley, M. S. Henderson, James M. Hitzrot, W. L. Keller, Frank R. Ober, D. B. Phenuster, Emmet Rixford, Charles L. Scudder and William O'Neill Sherman.

The plans of the committee for the Philadelphia Session comprise:

1. Plaster of Paris
2. Emergency treatment of fractures of the lower extremity
3. Compression fracture of the spine
4. Fracture of the radius—lower end
5. Active movements and massage in treatment of fractures

Demonstrations will be given in separate booths with human models. Demonstrators will be on duty from 9 a. m. to 5 p. m. continuously. Demonstrations will run concurrently and criticisms and questions will be answered in the booths.

The committee has arranged for the services of about one hundred physicians, who will aid in the continuous demonstrations. The names of the demonstrators will appear in the Philadelphia Number of THE JOURNAL.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a m on Monday, 10 45 on Tuesday, 9 15 on Thursday and 10 30 on Saturday over Station WBBM (770 kilocycles, or 389 4 meters).

The program for the week is as follows:

March 16 Dust
March 17 Anemia
March 19 Pottacosis
March 21 International Sanitary Relations

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12 05 p m, Central Standard Time.

The program for the week is as follows:

March 16 Underweight
March 17 Cheerfulness
March 18 The Great Composer — Sleep
March 19 Safe to Be Sick in a Hospital
March 20 The Health Item in Your Budget
March 21 Indicators of Medical Progress

CONTRIBUTIONS FOR MEDICAL SALON IN PERSHING HALL

The sum contributed this week for the Pershing Memorial in Paris brings the total to \$2,151 60. A list of those who have contributed during the current week follows:

A B Bruner M D Cleveland	George J Righter M D Alta
Fenwick Beelman M D New York	mont V Y
J D Worrell M D Monmouth	C C Massey M D Smithfield
Ill	N C
M Milton Eckert M D New York	J B Bostick M D Omaha

ARIZONA

Bill Introduced—H 239 to amend the nursing practice act proposes to provide for the issuance of licenses without examination, to all nurses who served for at least ninety days in the practice of their profession in the Army, Navy or Marine Corps during the World War.

CALIFORNIA

University of Southern California School of Medicine Not Approved—When this medical school was first opened the dean was enabled to secure a corps of well qualified teachers under the belief that other needed improvements would be made. For that reason at a business meeting of the Council on Medical Education and Hospitals of the American Medical Association held in June 1930 the Council voted that an acceptable rating be granted for the students who had completed their first two years of medical work during the years 1928-1929 and 1929-1930 under the faculty thus secured but that an acceptable rating for the medical school be withheld in the hope that further improvements deemed essential would be made. Recent information obtained from reliable sources however indicated that instead of making further improvements actually retrogressive measures had been adopted. At a business meeting of the Council held February 15 therefore the Council had no other alternative than to vote that an acceptable status for this medical school be not granted.

Society News—Dr Joseph R Shuman addressed the Los Angeles Obstetrical Society February 10 on "End Results in Children Born with Intracranial Injuries." —Dr August H

Rosburg addressed the San Francisco County Medical Society February 10 on "Bacteriophage." Harry E Alderson "Bacteriophage in Dermatology" and Edwin W Schultz, "Discussion of Experimental Results on Bacteriophage." —Dr H Gideon Wells Chicago, delivered the third annual series of medical lectures under the Colver Lectureship at the College of Medical Evangelists, Los Angeles, February 17-19 on the general subject "Nature and Cause of Cancer." —Dr Jules Duesberg rector and professor of anatomy University of Liege Belgium addressed the faculty and students of the University of California Medical School San Francisco February 24 on "How Belgium Is Trying to Develop Research." —Dr Lyell C Kinney addressed a joint meeting of the Imperial Valley and San Diego County medical societies El Centro February 14 on "Surgical Radiology." —Dr Everts A Graham St Louis delivered three lectures before the San Diego Academy of Medicine, March 3-5 on "The Empyema Question," "Pulmonary Suppuration and How Shall We Estimate and Improve the Operative Risk in Patients with Disease of the Biliary Tract." —The Irueder Society was addressed February 24 by John S Broadway professor of law and director of the legal and clinic University of Southern California Law School on "What Is Wrong with the Professions" and Dr Carl R Howson Los Angeles "The Future of Medicine." —Dr William J Kerr, San Francisco, addressed the Portland Academy of Medicine Portland, Ore, February 12 and the King County Medical Society February 9 at Seattle on "Recent Experimental Studies on the Peripheral Circulation with Special Reference to Raynaud's Disease."

CONNECTICUT

Diphtheria Decreases in New Haven—There was not a child's death reported from diphtheria in New Haven during 1930. Only fourteen cases occurred in a population of 162,655 which is about a 50 per cent reduction from the best previous record. One adult death was reported.

Department of Student Health at Yale—A new four story building erected at Yale University at an approximate cost of \$500,000 to house the Department of University Health was recently opened. The building of Indiana limestone is situated

ated on the southern extension of the Cross Axis. The first floor contains clerical offices and a suite of three rooms for women students. In the basement are x-ray equipment, three orthopedic offices, two physical therapy rooms, an isolation and a sterilizing room. The second floor is arranged to care for sick or injured ambulatory patients. Seven offices, three medical, two surgical, one for diseases of the eye and one for diseases of the ear, nose and throat are also on this floor. A total of 27,710 visits was made to this clinic service in 1929-1930. Examination suites, clinical laboratory and the sanitary inspector's office are on the third floor. The fourth floor contains two follow-up rooms, a large staff room, a residents' suite and the director's office. The university health department was organized in 1916 to promote the general health and physical fitness of students, to encourage habits of rational exercise and healthy living and to insure sanitary environment. A medical examination by the staff is required of each student at least once a year. The medical service not only takes care of communicable diseases and other illnesses but extends its supervision to mental hygiene, nutrition of underweight and overweight

students orthopedic corrections and the use of physical therapy. During the last year an effort was made to improve the mental hygiene technique used in the survey of new students. This service since its inauguration in 1927, has almost doubled, the number of students treated in that year being 470 and in 1930, 851. Emergency patrol stations were recently established near the dormitories, each one having a telephone and attendant on duty during the hours that the department offices are closed, permitting prompt communication with physicians on duty.

ILLINOIS

Bill Introduced—H 310 proposes to provide that in case of death occurring without medical attendance, it shall be the duty of the undertaker to notify the coroner of the death and that the coroner shall then make an investigation as to the cause of death.

License Restored—The state department of registration and education restored January 20 the license to practice medicine of Dr Elmer L Apple Albion. The license was revoked, Dec 20 1930 after Dr Apple was convicted of violation of the Harrison Narcotic Act.

Chicago

P A Kechek Goes to Jail—The Department of Registration and Education of Illinois issued a warrant February 3 against P A Kechek who was posing as a physician in Chicago, February 7. Kechek was arraigned in the municipal court and asked for a jury trial. On failure to produce bond he was sent to jail until his trial February 26. On that date Judge McCarthy found Kechek guilty of violating the medical practice act, sentenced him to an additional thirty days in jail, and also warned him not to violate the law again.

Society News—Dr Albert H Andrews among others, addressed the Chicago Laryngological and Otolological Society March 2 on "Indication for Operation in Acute Mastoiditis."—Dr William R Cubbins addressed the Chicago Society of Industrial Medicine and Surgery February 4 on 'Fractures of the Humerus,' and Dr Carl Scudari presented a Report of Five Hundred Consecutive Cases of Fracture of the Humerus in the Wards of the Cook County Hospital.—Dr Raymond W McNealy delivered the fifth annual Albert J Oschner Memorial address February 18 before a joint meeting of the Chicago Medical Society and its North Side Branch on 'Present Trend in Blood Vessel Surgery.'—Drs Fred M Smith and William D Paul Iowa City, among others addressed the Chicago Society of Internal Medicine, February 23 on 'Studies on the Mechanism of the Pain of Peptic Ulcer.'—A symposium on sterility was presented before a joint meeting of the Chicago Urological and Gynecological societies, February 26, the speakers being Drs Henry Schmitz and Victor D Lespinasse.—A symposium on diseases of the heart will be presented before the Chicago Medical Society March 18 by the following members of the faculty of Lovola University Medical School: Drs Thomas P Foley, Isadore M Trace and Italo F Volini. Mr Leonarde Keeler of the Scientific Crime Detection Laboratory, affiliated with Northwestern University, addressed the society, January 28, on "Practical Application of Emotional Changes."

INDIANA

Bills Introduced—S 284 proposes to authorize counties, certain cities, and districts composed of counties to establish and maintain full time health departments. S 324 proposes to prohibit the employment of nurses in hospitals longer than eight hours a day, except in emergencies. H 478 proposes to authorize cities of from 104,000 to 112,000 population to make appropriations to certain types of hospitals located therein. H 497 proposes to authorize cities of the second third fourth and fifth classes to establish departments of public sanitation.

Society News—Dr James O Ritchey Indianapolis addressed the Clinton County Medical Society, Frankfort February 5 on hypothyroidism.—Dr Clarence L Boel Muncie, addressed the Delaware-Blairford Counties Medical Society Muncie January 20 on intravenous ptyelography.—Dr Frank W Hartman Detroit addressed the St Joseph County Medical Society South Bend February 11 on Newer Aspects of the Nephritis Problem.—Meningitis in Children was the subject of Dr Arthur J Fletcher Danville Ill before the Fountain-Warren County Medical Society Hillsboro February 5.—Dr Edwin N Kime Indianapolis addressed the Gibson County Medical Society Princeton February 2 on 'Physical Therapy and Its Relation to General Practice.'

Dr Martin Dewey, New York addressed the Elkhart County Medical Association, Elkhart February 5, on 'Evolution and Development of the Heart and Face as Related to Certain Determinants.'—Dr Alfred S Giordano, South Bend addressed the LaPorte County Medical Society February 19 Michigan City on 'Undulant Fever.'—Dr Edward L Lingeman Indianapolis addressed the Wayne Union County Medical Society Richmond, February 19 on 'Common Colds.'—Dr Amzi Weaver, New Albany, addressed the Floyd County Medical Society, February 13 on 'Pulmonary Edema' with report of case.—Mr Albert Stump Indianapolis attorney for the state medical association addressed a joint meeting of the Muncie Bar Association and the Delaware-Blairford Counties Medical Society, Muncie February 17 on 'Expert Evidence in the Courts.'—The Indianapolis Medical Society will be addressed March 14 by Drs Robert M Darmin on 'Jugular Bulb Thrombosis with case report,' and Joseph W Rielletts 'Intragastric Photography.' The society will be addressed, March 24 by Dr David Smith on 'Conduct of Labor in Borderline Pelvis' and March 31 by Drs Edwin N Kime and Percy E McCown 'Status of Biophysics in Modern Medical Practice' and 'Discussion of the Etiology and Possible Prevention of Prostatic Hypertrophy,' respectively.

IOWA

Award for Service to Community—Dr and Mrs David Wilson Smouse formerly of Des Moines, now of Pasadena Calif received jointly the award given annually to the citizen of Des Moines who has given the greatest service to the community. It is commemorated by the presentation of a loving cup furnished by the Des Moines Tribune Capital. Dr and Mrs Smouse in 1929 gave \$330,000 for the founding of a school for handicapped children in Des Moines. The school which is to be known as the David W Smouse Opportunity School was to be opened to students March 9. It is to be operated as a part of the city school system and will care for children with orthopedic defects, deafness, defective vision, cardiac impairment and chorea. Mentally handicapped children are not to be admitted. Dr Smouse who is 77 years old engaged in practice in Des Moines for about forty years.

Society News—Dr Harold M Camp, Monmouth Ill addressed the Des Moines County Medical Society February 10 on 'How Public Health Education Affects the Physician.'—The sixth annual meeting of the Iowa Public Health Association will be held April 23, in Des Moines with headquarters at the Hotel Fort Des Moines. Drs Talruero Clark, Washington D C, and Arthur T McCormack Louisville, Ky will be the guest speakers.—Drs John L Kestel and Thomas F Thornton both of Waterloo addressed the Des Moines Academy of Medicine and the Polk County Medical Society January 27, on 'Objective Diagnostic Methods in Kidney Disorders' and 'Stone in the Ureter' respectively. Dr Irl C Riggan New York, addressed the society, February 25, on 'rheumatic heart disease in children.'—The annual meeting of the Iowa Tuberculosis Association, the Iowa Sanatorium Association and the Iowa Heart Association was held in Des Moines, February 26-27. Among the speakers were Drs Walter L Bierring, Des Moines, Irl C Riggan New York, Henry Boswell, Sanatorium Miss and Edward A Meyerding, St Paul.—Dr Warren H Cole, St Louis spoke before the Linn County Medical Society Cedar Rapids January 6 on 'infections of the liver.'—Dr Anthony C Pfohl addressed the Johnson County Medical Society, Iowa City, February 4, on 'acute intestinal obstruction.'—Dr Henry Schmitz Chicago addressed the Marshall County Medical Society January 6 on 'early diagnosis of cancer.'—Dr Dean M Lierle Iowa City, addressed the Scott County Medical Society Davenport, January 6, on 'allergy in relation to otolaryngology.'

KANSAS

Bill Introduced—S 379 proposes to require all chiropractors to register annually and to pay an annual fee of \$5.

LOUISIANA

Medical School for Louisiana University—Organization of a school of medicine as a part of Louisiana State University has recently been announced by Gov Huey P Long. Pre-medical work and the first two years of medicine are to be given at the university in Baton Rouge and the last two in connection with Charity Hospital New Orleans. Dr Arthur A Vidrine superintendent of Charity Hospital has been named dean and an advisory directorate has been appointed, consisting

of Drs James T Nix Jr, New Orleans, Arthur A Herold, Shreveport, and Dempsey C Iles, Lake Charles. Reported appointments to the teaching staff include Drs Clyde Brooks, at present professor of physiology and pharmacology at the University of Alabama School of Medicine, Tuscaloosa, who will occupy the same position in the new school, Henry N Blum, professor of clinical ophthalmology at Tulane University of Louisiana Graduate School of Medicine, head of the department of ophthalmology, Joseph N Roussel president of the staff of Touro Infirmary, head of the department of dermatology, Pierre Jorda Kahle, professor of urology at the graduate school of Tulane, head of the department of urology, Phillips J Carter, assistant professor of operative gynecology in the graduate school of medicine at Tulane head of the department of obstetrics, Russell E Stone New Orleans, who will be professor of clinical surgery in the new graduate school, Homer J Dupuy, Jr, professor of oral surgery, Loyola University, New Orleans, head of the department of otolaryngology, and Amedee Granger, head of the department of radiology at the graduate school of medicine at Tulane who will head a similar department in the proposed school. Construction of a new building for the medical school on the Charity Hospital grounds is expected to start about April 1 and the school will receive students next October, according to the plans.

MAINE

Bill Introduced—H 443 proposes to make it unlawful to sell any food, drink, medicine or toilet preparations intended for human use, or any antifreeze agent for motor vehicle radiators, which contains wood alcohol, methanol or methyl alcohol. Poison for other purposes may be made only in containers labeled "poison."

Society News—Dr Robert B Osgood, Boston, conducted postgraduate teaching clinics and lectured on arthritis at the Central Maine General Hospital Lewiston in January. —Dr Edward H Risley, Waterville delivered the annual president's address at the December meeting of the Kennebec County Medical Society on 'Traumatic Head Injuries'. —Dr Frederick T Lord, Boston, addressed the Penobscot County Medical Society, Bangor, in December, on pulmonary disturbances. —Drs William P Murphy and Samuel A Levine both of Boston, gave addresses before the York County Medical Society Biddeford January 8, on 'Diet in Disease' and 'Interpretation of Cardiac Irregularities,' respectively.

MARYLAND

Bills Introduced—H 182 proposes to provide that local boards of health shall each appoint in May 1931 and quadrennially thereafter, a health officer. No such appointment however, shall be made without the advice and consent of the state board of health. H 183 proposes that the state board of health shall divide the state outside of Baltimore city into twenty three sanitary districts and shall appoint a deputy health officer for each sanitary district.

Dr Frost to Succeed Dr Howell—Dr Wade Hampton Frost professor of epidemiology Johns Hopkins University School of Hygiene and Public Health, has been appointed dean of the school to take office July 1, when Dr William H Howell retires as director. In creating a deanship to take the place of the directorship, the university adopted a new ruling under which the dean is appointed for three years and is not eligible to succeed himself. Dr Frost was graduated from the University of Virginia Department of Medicine in 1903 and served on the staff of the U S Public Health Service for many years. In 1919 he went to Johns Hopkins as lecturer in epidemiology and became professor in 1921.

MICHIGAN

New Ruling on Internships—The Michigan State Board of Registration in Medicine has recently adopted a new rule under which two years service on the staff of an approved hospital for tuberculosis or for mental disease will be accepted in lieu of the present requirement of a one year rotating internship in a general hospital. This plan will make it possible for a physician intending to limit himself to these specialties to begin his chosen work immediately after graduation and it is hoped that more physicians will thus be induced to enter these fields.

Bills Introduced—H 144 proposes that any person arrested while driving a motor vehicle on public highways and charged with being intoxicated or under the influence of stupefying drugs may be taken by the arresting officer to a duly licensed

physician for examination, and the testimony of the examining physician shall be admitted at the trial. H 413 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic, defined as the locating of misaligned or displaced vertebrae of the human spine and the procedure preparatory to, and the adjustment by hand of such misaligned or displaced vertebrae and adjacent bones or tissues.

Society News—Mackinaw City, a village of 800 persons, was left without a physician when Dr Allen C Tiffany recently departed on account of ill health. The nearest physician is said to be in Cheboygan 20 miles away. —Dr Emil Amberg, Detroit, addressed the Bay County Medical Society, Bay City, January 14 on the hard of hearing child and the deaf child. —Dr Richard R Smith, Grand Rapids, addressed the Calhoun County Medical Society, Battle Creek, February 3 on 'Uterine Myomata and Their Treatment'. Dr Raphael Isaacson, Ann Arbor, addressed the society January 6 on 'Diagnosis and Treatment of the Blood Forming Organs'. —Dr Leo L Newfield addressed the Monrovia Medical Society, Detroit February 2, on 'Cardiac Pain and Coronary Disease' and Dr Sydney K Beigler February 9 on 'Chronic Pulmonary Suppuration'. —Drs Guy L Hunner, Baltimore, and William E Lower, Cleveland, addressed a joint meeting of the Detroit Roentgen Ray and Radium Society and the Detroit Academy of Surgery January 8 on 'Renal Hemorrhage' and 'Tumors of the Kidney and Their Surgical Treatment'. —Dr Norman R Kretzschmar, Ann Arbor addressed a recent meeting of the Monroe County Medical Society at Monroe on 'Abnormal Bleeding in Obstetrics and Gynecology'. —Dr John E Gordon, Detroit, addressed the Oakland County Medical Society, Pontiac, February 19 on 'Prevention and Treatment of Measles' and 'Diagnosis and Treatment of Preparalytic Poliomyelitis'. —A joint meeting of the Wayne County Medical Society and the Detroit Dental Society, February 10 was addressed by Drs Robert C Moehlig on 'Effect of Glutular Disturbances on the Teeth', Plinn F Morse, 'Relation of the Teeth to General Pathology' and Frederick Schreiber, 'Convulsions'. Dr Max Ballin addressed the Wayne County Medical Society, February 17, on 'Bone Changes Caused by Parathyroidism and Parathyroidectomy'. Dr Frank C Mann, Rochester, Minn, March 3, on 'Physiology of the Liver', and Dr William Engelbach St Louis, March 10 on 'Endocrines'. Dr John F Barnhill, Indianapolis will speak March 17 in a joint meeting with the Eye, Ear, Nose and Throat Society, on headache. Dr Willis F Manges Philadelphia, will address the society in conjunction with the Detroit branch of the American Roentgen Ray and Radium Society, March 24, on 'Foreign Bodies in Air Passages'.

MINNESOTA

Bills Introduced—H 529 proposes to provide that in the admission of patients to the Minnesota General Hospital preference shall be given to patients at the Hospital of the Minnesota State Soldiers' Home. H 569 proposes that any person who is a licensed assistant pharmacist at the date of its enactment who was actually employed in a drug store prior to April 23 1919, and who prior to the passage of the bill has duly applied for a license as a pharmacist shall be entitled to registration as a pharmacist on passing a satisfactory examination and the payment of the proper fee.

Naturopath Fined—William H Hirst, 53 years old, self-styled naturopath pleaded guilty in the district court, February 26 on charges of maintaining an office and using the title 'doctor' in violation of the basic science law, the state board of medical examiners reports. Judge John W Boerner sentenced him to pay a fine of \$500 or serve six months in the workhouse for the first charge. On the second charge he was sentenced to one year in the workhouse but the sentence was suspended on condition that he refrain from practicing, healing in Minnesota. Hirst paid the fine.

MISSOURI

Radium Reclaimed from Watch Dials—Students at the University of Missouri under the direction of Herman Schlundt, PhD professor of physical chemistry are reclaiming radium from old luminous watch and clock dial paint. By a process of removing the impurities of the paint by gradual crystallization and precipitation it is said that about 95 per cent of the radium is recovered. About 50 mg can be extracted from 100 gallons of paint. The laboratory is principally engaged in the refining of molybdenum and incidentally in the separation and conservation of other radioactive substances and by other

departments of the university in studies of the effects of radiation. Experiments are also in progress to determine the hazards incident to the handling of radioactive substances.

Bills Introduced—H 583 proposes to make it unlawful for any itinerant vender to sell or in any other way distribute any drug, nostrum, ointment or application, whether intended for the treatment of disease or injury or not. Nothing in the act, however is to apply to licensed practitioners of medicine, surgery, dentistry, veterinary surgery or medicine, homeopathy or pharmacy. H 584 proposes to require employees in hotels, restaurants, cafes and lunch rooms to undergo such physical examinations at least once every six months, as will indicate freedom from infectious, contagious or chronic diseases. H 589 proposes to grant the state board of health general supervision of all nervous and mental hospitals and all institutions treating nervous and mental diseases. H 617 proposes to authorize the establishment of a psychopathic hospital, in two units of approximately 100 beds each, at a cost not to exceed \$1,400,000.

NEW MEXICO

Bill Introduced—S 94 proposes a new act to regulate the manufacture, possession, use, control and disposal of certain narcotic drugs.

Dr Earp Appointed State Health Officer—Dr J Roslyn Earp, formerly of Boulder Colo., has been appointed director of the bureau of public welfare of New Mexico, succeeding Dr George Sparr Lockett, who resigned several months ago. Dr Earp, a native of England, was recently scientific editor of *Colorado Medicine*.

NEW YORK

Society News—A conference of health workers called by Dr Thomas Parran, Jr., state health commissioner, was held at Albany, January 21, to outline a campaign for reducing the number of cases of measles among children under 3 years of age. —Dr John S McCormick, Albany, among others, addressed the Albany County Medical Society, January 11, on 'Congenital Absence of a Portion of the Esophagus.' Drs Jonathan M. Wainwright, Scranton, Pa. and Burton T. Simpson, Buffalo, addressed the society, February 27 on 'Importance of the Tumor Clinic in the Solution of the Cancer Problem' and 'Responsibility of the General Practitioner in the Early Diagnosis of Cancer,' respectively.

Outbreak of Gastro-Enteritis Traced to Well Water—Following a supper at which about 100 people were served in a community in the northern part of the state, Dec 11, 1930, many persons who had partaken of the meal suffered attacks of vomiting, pain, diarrhea and exhaustion. Most of the patients recovered in from two to five days. Forty feet away and at a slight elevation above a well from which the water for the meal was taken there was a privy. Investigation showed that a member of the household residing on the property had had a severe attack of gastro enteritis three weeks prior to the supper, and one week later another member of the family had a like illness. The symptoms in both cases were similar to those of the persons who became ill after the supper. A sample of water from the well examined at the state laboratory was found to be polluted. *B. dysenteriae* of both the Flexner and the Sonne types were isolated at the state laboratory from specimens of feces submitted from those who were ill.

New York City

Sixth Harvey Lecture—Dr James B. Herrick, emeritus professor of medicine, Rush Medical College, University of Chicago will deliver the sixth Harvey Society Lecture March 19 at the New York Academy of Medicine on 'The Coronary Artery in Health and Disease.'

Physicians as Artists—Oil paintings, water colors, photographs, etchings, linoleum cuts, sculpture and wood carvings are among the varied work shown at the fifth annual art exhibit sponsored by the New York Physicians' Art Club at the New York Academy of Medicine. Among the sixty-three exhibitors are Drs Benjamin S. Barringer, president of the club who is showing three oil paintings, Solomon Bauch and Louis C. Schroeder, oil paintings. Henry S. Patterson and Henry A. Bancel, marines and landscapes in water color, Carlo D. Martignetti, Orange N. J., snow scene in oil. Harris P. Mosher, Boston, etchings and wood carvings. Isaac Seth Hirsch, sculpture. Max Thorek, Chicago. Theron W. Kilmer and Lionel S. Aufer, photographs and H. Fischer, linoleum cuts and etchings. Except for one of Dr Barringer's paintings, one of

a gnarled tree, which he named "Arteriosclerosis," there is no reference to medicine in the exhibition, in which there are 233 individual exhibits.

Diphtheria Decreased 57 Per Cent in 1930—The lowest death rate for diphtheria on record in New York is shown in the report of the commissioner of health for 1930. There were during the year only 199 deaths, a decrease of 57 per cent from 1929, and 3,806 cases as against 8,548 in 1929. The reduction is attributed to the concentrated drive made by the special commission during 1929 and 1930. The death rate from measles showed a striking decrease, 153 deaths as compared with 1038 in 1928, the last epidemic year. This was the result of extensive use of convalescent serum, the commissioner reported. Two cases of smallpox were reported with no deaths; there have been only two deaths from smallpox in New York in eighteen years. Cancer showed the highest death rate on record in the city, 116 per hundred thousand. Heart disease showed a decrease of 527 deaths from the preceding year. The general death rate was 10.76, a slight decrease, and the infant rate was 57 per thousand births. There were no epidemics in 1930.

Society News—A total of 3,590 pints of human blood was transfused during 1930 from donors enrolled in the Blood Transfusion Betterment Association; it is reported 3,056 transfusions were made, for which approximately \$170,000 was paid. There are 800 professional blood donors registered in the association. —The Harlem Medical Association celebrated the sixtieth anniversary of its founding at a dinner, February 26. Dr Charles Gordon Heyd gave an address on 'The Future of Medicine' and Dr Louis I. Harris, on 'Medicine and Society.' —Dr Henry F. Graham addressed the Medical Society of the County of Kings, February 17 on the value of early operation for acute cholecystitis. —The New York Academy of Medicine was addressed March 5 by Drs Charles A. Elsberg on 'The Edwin Smith Surgical Papyrus and the Diagnosis and Treatment of Injuries to the Skull and Spine 5,000 Years Ago.' —Dr Foster Kennedy addressed the International and Spanish Speaking Physicians, Dentists and Pharmacists, February 27 on 'The Nature of Epilepsy,' and Dr Miran B. Proungian on syphilis. —Dr Ralph Pemberton, Philadelphia, addressed the New York Physical Therapy Society, March 4, on 'Physiologic Action and Therapeutics of Massage.' —Dr Reuben Ottenberg delivered the fifteenth afternoon lecture at the New York Academy of Medicine March 6 on 'Practical Advances in the Study of the Liver and Its Diseases,' and Dr Henry K. Pancoast, Philadelphia, the sixteenth March 13 on 'Silicosis: Its Present Aspect.' —Dr Joseph C. Bloodgood, Baltimore, addressed the Medical Society of the County of Queens March 6 on the opportunities offered to county medical societies by the developments of modern medicine.

OHIO

Athletic Coaches Must Take Health Courses—Athletic coaches in Ohio will henceforth be considered teachers of health and education in the eyes of the division of certification; the state department of education has announced. As such they must have a minor of twelve semester hours in health and physical education for part time work and a major of forty semester hours for full time. The ruling does not affect those who now hold certificates but is expected to be in full force by 1935.

Bills Introduced—S 186, to amend the workmen's compensation act, proposes to add to the list of those occupational diseases already compensable manganese dioxide poisoning, radium poisoning, tenosynovitis and prepatellar bursitis, chrome ulceration of the skin or nasal passages, potassium cyanide poisoning and sulphur dioxide poisoning. S 212 and H 266 propose to authorize physicians to prescribe pure grain or ethyl alcohol or spirituous liquor in quantities now or hereafter permitted by federal statutes and regulations. S 245 authorizes the state board of health to appoint inspectors of dairies and of slaughter houses and such other persons as are necessary to carry out the provisions of the code relative to the inspection of foods and supplies and to grant them general police powers. S 247 proposes to authorize physicians to prescribe not more than one pint of liquor in a ten day period to a patient and prohibits the prescribing of wine containing more than 21 per cent of alcohol by volume.

Personal—Dr Floyd R. Stamp, Alliance has been appointed health commissioner of Stark County; it is reported to succeed Dr Chester M. Peters, Canton, who resigned after eleven years.

service, to devote his time to private practice—Dr George E. Hollansbee was elected president of the Cleveland Medical Library Association, January 19. Dr Ales Hrdlicka, Washington, D. C., addressed the meeting on "Disease, Medicine and Surgery in Prehistoric America"—Dr William Edgar Wheatley, Lorain, was recently selected as the recipient of the 1930 Achievement Award presented by the Lorain Journal to the town's most valuable citizen. Dr Wheatley has practiced in Lorain for thirty years—Dr John S. Hagen, Cincinnati was recently appointed a member of the state medical board of Ohio to succeed the late Dr John K. Scudder—Dr George W. Crile, head of the Cleveland Clinic and professor emeritus of surgery at Western Reserve University School of Medicine was the guest of honor at a dinner given by about 400 physicians, February 23. Dr Charles H. Mayo, Rochester, Minn. was the principal speaker—Dr Joseph H. Kinnaman, chief medical inspector and assistant health officer of Cincinnati has resigned to become deputy health commissioner of Iowa—Dr John Dean Boylan, Milford Center, has been appointed health commissioner for Union County to finish the term of Dr Harry G. Southard, Marysville, who resigned to become state health officer—Dr Loy C. Schiff, Ashville, has been named health commissioner of Pickaway County to succeed the late Dr Addison L. Stump—Dr Millard C. Hanson, Mansfield was appointed health commissioner of Mansfield and Richland County to succeed Dr Theodore R. Meyer, who resigned, March 1.

OKLAHOMA

Bills Introduced—S. 127, to amend the narcotic act proposes to include in the list of those substances classed as narcotics "marijuana, or a preparation known as such cannabis from the plant cannabis sativa, family Moraceae its preparations or derivatives." H. 300 proposes to make it a cause for divorce for one spouse to be found incurably insane and committed to an institution for the treatment of insane persons.

Society News—Dr Henry H. Turner, Oklahoma City, among others, addressed a joint meeting of the Okmulgee and Okfuskee county medical societies, January 19, on "Relationship Between Neurology and Endocrinology"—Dr William P. Fite, Muskogee, addressed the Pottawatomie County Medical Society at Shawnee, January 17, on arthritis. Dr Willis Kelly West, Oklahoma City, presented a motion picture on "The Technique of Arthrodesis of the Hip Joint by Surgical Procedure."

OREGON

University News—Dr Eleonora T. Bell, professor of pathology, University of Minnesota Medical School delivered the N. W. Jones Lectures under the auspices of the University of Oregon Medical School, March 4-6. Dr Bell's topics were "Glomerulonephritis," "Nephrosis" and "Vascular Diseases of the Kidney."

Bills Introduced—S. 332 proposes that any registered pharmacist who has been paying annual renewal fees for twenty years or more and who is not actively engaged in the practice of pharmacy shall be carried in good standing without further payment until such time as he again enters active practice. S. 340 proposes to provide that the board of pharmacy may issue a certificate of registration to any person residing in the state for at least ten years, who has had at least ten years experience under the supervision of a registered pharmacist. S. 350, to amend the medical practice act proposes that when any woman furnishes the board of medical examiners with a sworn statement that any licensee has performed an abortion on her, the board shall immediately forward such sworn statement to the proper district attorney.

PENNSYLVANIA

Society News—Dr William A. Frontz, Baltimore, addressed the Cambria County Medical Society, February 12, on "The Diagnosis of Hematuria"—Dr Elmer H. Funk, Philadelphia, addressed the Northampton County Medical Society, February 20, on "Problems in the Diagnosis of Thoracic Disease"—Dr William D. Stroud, Philadelphia, addressed the Lehigh Valley Medical Association, Hazleton, February 11, on treatment of cardiovascular disease—Infection of the teeth and its relation to systemic disease was the subject of discussion at a joint meeting of the Erie County medical and dental societies, February 11, at which Dr Werner J. Rose, Buffalo, N. Y., and Thomas J. Hill, D.D.S., Cleveland, Ohio, were the principal speakers—Dr William Gerry Morgan, Washington, D. C., addressed the Lecoming County Medical Society, Wil-

transport in January, on "Some Observations on Etiology." At a meeting, February 13, Drs. Frederick E. Keller, Philadelphia, and John A. Campbell addressed the society on "Pelvic Surgery with Low Hemoglobin" and colitis, respectively—Dr George F. Suker, Chicago, addressed the Pittsburgh Ophthalmological Society, February 23, on "Retinal Complications in Cardiovascular Lesions"—Dr Howard S. Reiter, Brownsville, addressed the Fayette County Medical Society, among others, March 5, at Uniontown, on dystocia.

Philadelphia

Da Costa Day—Dr John Chalmers Da Costa, Samuel D. Gross professor of surgery, Jefferson Medical College, delivered a lecture reviewing his forty years' active work in surgery as the principal feature of the first observance of Da Costa Day by the Philadelphia County Medical Society, March 11. Da Costa Day was inaugurated, April 30, 1930, with the establishment of the John Chalmers Da Costa Foundation for the purpose of furthering postgraduate teaching under the auspices of the society.

Society News—Dr Damaso de Rivas gave the weekly seminar lecture under the auspices of the Philadelphia County Medical Society, February 27, on "Parasitology from the Clinical Standpoint." Dr John A. McGinn was the speaker, March 6, on "Responsibility of the Obstetrician in the Recognition and Treatment of Thymic Disorders in New-Born Babies"—Dr Herbert T. Kelly addressed the Philadelphia Medical Examiners Association, March 2, on "Significance of Sugar in the Urine"—Drs. Robert H. Ivy and Lawrence Curtis addressed the Philadelphia Academy of Surgery, March 2, on "Fractures of the Upper Jaw and Maxilla Bone," and B. Franklin Buzby, "Internal Derangements of the Knee"—Dr Francis V. Gowen addressed the Philadelphia Laryngological Society, March 3, on "Scarlet Fever Sinusitis"—Dr Catherine Macfarlane addressed the Obstetrical Society of Philadelphia, March 5, on "Carcinoma Developing in a Myomatous Uterus Following X-Ray Menopause."

SOUTH DAKOTA

Bill Introduced—H. 42, to amend the workmen's compensation act, proposes to raise to \$200 the amount for which an employer will be liable on account of medical and hospital services rendered an injured employee and to provide that in exceptional cases the employer shall furnish such additional medical, surgical and hospital services as the industrial commission shall order, but in no event to exceed an additional \$100.

TENNESSEE

Health at Nashville—Telegraphic reports to the U. S. Department of Commerce from eighty-one cities with a total population of 36 million for the week ended February 28 indicate that the highest mortality rate (25.8) appears for Nashville and the rate for the group of cities as a whole, 14. The mortality rate for Nashville for the corresponding period in 1930 was 13.9 and for the group of cities 14.1. The annual rate for the eighty-one cities for the nine weeks of 1931 was 14.2 as compared with a rate of 13.4 for the corresponding weeks of 1930. Caution is necessary in the interpretation of these figures as weekly figures fluctuate widely. The fact that some cities are hospital centers for large areas outside the city or that they have large Negro populations may tend to increase the death rate.

TEXAS

Bills Introduced—H. 569 proposes that the state require the Texas Dental College located in Houston and operate it as a state school of dentistry under the same name. H. 692 proposes to authorize the establishment of a tuberculosis sanatorium for Negroes.

UTAH

Bill Introduced—S. 103 to amend the optometry practice act proposes to add to the list of grounds for the revocation of licenses (1) soliciting from house to house or sending a solicitor from house to house and (2) failure to deliver a certificate of identification as required by the act. It also proposes to make it a misdemeanor to sell at retail as merchandise in any store or established by mess any spectacles, eyeglasses or lenses unless a duly licensed physician or duly qualified optometrist is in charge of and in personal attendance at the place where the articles are sold.

WISCONSIN

Personal—Dr Merle R. French resigned February 7, as director of the contagious disease division of the Milwaukee health department. He has been appointed state epidemiologist of New York; it is reported—Dr Norman L. Howison has resigned as attending physician at the Dunn County Asylum and County Home Menominee after thirty years' service.

Society News—Dr Harry R. Foerster was recently elected president of the Milwaukee Academy of Medicine and Dr David F. W. Wenstrand, secretary. Dr William S. Middleton, Madison, discussed pernicious anemia and Dr Carl W. Eberbach, injection treatment for varicose veins, before the Milwaukee County Medical Society, February 13. Dr Charles F. Sawyer, Chicago, addressed the Outagamie County Medical Society, Appleton, February 19, on intestinal obstruction. Dr Joseph W. Gale, Madison, addressed the Marathon County Medical Society, Wausau, February 18, on diseases of the breast. Dr William S. Middleton, Madison, addressed the Green Lake Waushara Adams County Medical Society, recently, on 'Clinical Interpretation and Treatment of Nephritis'. Dr Jules Duesberg, professor of anatomy and rector at the University of Liege, Belgium, addressed the University of Wisconsin Medical Society and the biologic division of the university, February 9-10, on 'Experimental Cytology'. George L. Clark, Ph.D., professor of chemistry, University of Illinois, will address the society, March 18, on 'Analysis of Tissue by X Rays'.

GENERAL

Four Weeks of Automobile Fatalities—Eighty-one large cities in the United States reported to the U. S. Department of Commerce 614 deaths from automobile accidents during the four weeks ended February 21, as compared with 574 deaths during the four weeks ended Feb. 22, 1930. Most of these deaths resulted from accidents within the corporate limits of cities, although some accidents occurred outside the city limits. The number of deaths within city limits was 515 contrasted with 491 for the corresponding period of 1930. For the fifty-two week periods ended February 21 and Feb. 22, 1930, the totals for the eighty-one cities were respectively, 8,937 and 8,668, which indicate a recent rate of 25.6 per hundred thousand of population as against an earlier rate of 25.3. Eight cities reported no deaths from automobile accidents during the four weeks compared with five cities for the corresponding period in 1930.

"Jake" Paralysis Still Being Reported—The U. S. Public Health Service recently announced that cases of jamaica ginger paralysis are still occurring in the United States. It was announced some time ago that the cause of jamaica ginger paralysis had been determined to be triorthocresyl phosphate, which evidently had been used as an adulterant in the manufacture of jamaica ginger extract. It is desired to give publicity to the fact that all persons should avoid the use of jamaica ginger extract as a beverage. No cases of this poisoning have been reported in connection with the use of any other ginger products or preparations; it is reported, the cases observed having been associated with the improper or illicit use of jamaica ginger extract. It had not been determined February 16 whether the recent cases had been caused by the use of the older preparation or whether it is a new product being marketed by unscrupulous manufacturers. Newspapers February 3 reported twenty-five cases in Los Angeles and thirty cases were reported March 3 among inmates of the National Soldiers Home Hospital at Sawtelle, Calif.

Medical Bills in Congress—S. 255, the Jones maternity, infant and rural hygiene bill, failed of passage, its proponents having been unable to secure a vote in the Senate on the substitute bill passed by the House. S. 1812 has been signed by the President authorizing the collection of annual statistics relating to crime and to the defective, dependent and delinquent classes. S. 5139 has been signed by the President extending the provisions of certain laws relating to vocational education and civilian rehabilitation to Porto Rico. S. 5659 has been signed by the President authorizing the purchase by the federal government of the state laboratory at Hamilton, Mont., constructed for the prevention, eradication and cure of spotted fever. S. 6171 has been signed by the President regulating the prescribing and use of waters from the Hot Springs National Park at Hot Springs, Ark. H. J. Res. 480 has been signed by the President authorizing an appropriation to defray the expenses of participation by the United States in the Conference on the Limitation of the Manufacture of Narcotic

Drugs to be held at Geneva, Switzerland, May 27. H. R. 16982 has been signed by the President, authorizing an appropriation of \$20,877,000 to provide additional hospital, domiciliary and outpatient dispensary facilities for persons entitled to hospitalization under the World War Veterans' Act, 1924, as amended.

Society News—The annual meeting of the recently organized Western Branch of the American Public Health Association will be held in Seattle, May 28-30, with headquarters at the Olympic Hotel. Local arrangements are in charge of Dr Ernest T. Hanley, city health officer. The secretary is Dr William P. Shepard, 600 Stockton Street, San Francisco. The Medical Library Association will hold its annual meeting, May 19-21, in New Orleans. At the annual meeting of the Tri-State Medical Association (Tennessee, Mississippi, Arkansas), February 17-20, Dr Andrew G. Payne, Greenville, Miss., was installed as president, and Dr Lowry H. McDaniel, Tyrone, Ark., was made president elect. On the program were Drs William B. Coley, New York, Russell L. Haden, Cleveland, and Theodore C. Hempelmann, St. Louis. John Shelton Horsley, Richmond, Va., Cyrus C. Sturgis, Ann Arbor, Mich., and William Gerry Morgan, Washington, D. C., The association which is in its forty-seventh year, changed its name to the Mid-South Post-Graduate Medical Association. Dr Beverley R. Tucker, Richmond, was elected president of the Tri-State Medical Association of Virginia, North Carolina and South Carolina at its thirty-third annual meeting, February 16-17, at Richmond. The next meeting will be in Raleigh, N. C. Homer N. Calver, for seven and a half years executive secretary of the American Public Health Association, resigned January 1. W. Frank Walker, D. P. H., a member of the association's staff, is acting executive secretary pending the appointment of Mr. Calver's successor.

Bequests and Donations—The following bequests and donations have recently been announced:

Jewish Hospital, Philadelphia, \$10,000 by Mrs. Henry Fernberger. Philadelphia to defray the expense of equipping a new electrotherapeutic department.
Long Island College Hospital, Brooklyn, \$25,000 by the will of the late Percy S. Dudley.
New York Institute for the Deaf and Dumb, \$5,000 by the will of its late president Samuel Rositer Bitts.
Ebronon Hospital, Beth Israel Hospital and Jewish Memorial Hospital, all of New York, each \$5,000 by the will of the late Abraham Savada.
Long Island College Hospital Alumnae Association, \$30,000 by the will of the late Miss Anna M. Wilbur.
Fifth Avenue and St. Luke's hospitals, New York, each \$100,000 by the will of the late Adolph L. Condrin.
Jewish Hospital, \$10,000 and \$500 each to the University, Jefferson and Temple hospitals, all of Philadelphia, by the will of Henry L. Weinberger.
Jefferson Medical College, \$30,000 for the establishment of four scholarships for the education and maintenance of deserving young men whose means are limited, by the will of Dr. William T. Hamilton.
All Souls and Morristown Memorial hospitals, Morristown, N. J., each \$25,000 by the will of Gertrude I. Thebaud.
Hackensack Hospital, Hackensack, N. J., and Passaic General Hospital, Passaic, each \$25,000 by the will of Frederick L. Adams.
Willard Fillmore Hospital, Buffalo, \$25,245.23 for the establishment of a memorial, by the will of the late Dr. Francis Marion Rich.
Maryland School for the Blind, Overlea, and the Hospital for Consumptives of Maryland, Towson, each \$10,000 and the Presbyterian Eye, Ear and Throat Charity Hospital, Baltimore, each \$5,000 by the will of Miss Margaret E. Maund, Baltimore.
Women's and Harper hospitals, Detroit, each \$2,500 by the will of Richard P. Joy.
Johns Hopkins Hospital, \$50,000 in addition to sharing with Johns Hopkins University in the ultimate distribution of the residue of the estate at which time the institution will receive \$700,000. Children's Hospital School, Baltimore, and Hospital for Consumptives of Maryland, Towson, each \$10,000 and the Baltimore Eye, Ear and Throat Hospital, \$2,500 by the will of the late Mr. William A. Marbury.
Union Memorial Hospital, Hospital for the Women of Maryland and Johns Hopkins Hospital, Baltimore, will receive one-half, three-tenths and two-tenths respectively of the major portion of a \$600,000 estate by the will of the late Francis Burns Harvey, Baltimore.
Roosevelt Hospital, New York, \$10,000. New York Skin and Cancer Hospital and St. Mary's Free Hospital for Children, \$5,000 each and St. Luke's Hospital, New York, \$3,000 by the will of the late Mrs. David H. Lydig.
Monmouth Memorial Hospital, Long Branch, N. J., Stony Wold Sanatorium, Lake Kuschka, N. Y., and Montefiore Hospital, New York, each \$3,000 and Mount Sinai Hospital, New York, \$7,500 by the will of the late Mrs. Edgar J. Kahler.
University of Texas, Galveston, \$10,000 by the will of the late Dr. Benjamin O. Thrasher. El Paso, the amount to be used for the medical department of the university. Dr. Thrasher's preference was that the sum be used in connection with the chair of mental diseases in the university.
Jewish, Jefferson and Pennsylvania hospitals and the Federation of Jewish Charities, all of Philadelphia, each \$1,000 by the will of the late Joseph E. Sulzberger.
University of Chicago, about \$1,000,000 for medical research. Michael Reese Hospital, \$500,000. Jewish Charities of Chicago, \$50,000. St. Luke's Hospital, \$10,000. All of Chicago and National Jewish Hospital for Consumptives, Denver, \$5,000 by the will of the late Albert Kuppenheimer.
Wilmington General Hospital, Wilmington, Del., \$200,000 for the building of a contagious disease ward from Mr. and Mrs. Irene du Pont.

Cermantown Dispensary and Hospital Philadelphia \$30 000 as a fund to found free beds in the men and women's wards by the will of Miss Helen Huber
Hahnemann Medical College and Hospital Philadelphia \$100 000 outright and \$10 000 for endowing beds by the will of the late Miss Fanny Augusta Shortridge
Prebyterian Hospital Philadelphia \$20 000 by the will of Col William J Elliott
Hospital for Joint Diseases New York \$1 000 000 Mount Sinai and Lebanon Hospitals New York St Joseph's Hospital Far Rockaway and National Jewish Hospital for Consumptives Denver each \$5 000 Monte fiore Hospital \$10 000 Bar Moriah Hospital and Beth Israel Hospital New York each \$2 500 by the will of the late Alfred M Heinsheimer

Government Services

Army Personals

Majors Frank N Stiles and Wayne R Beardsley and Capts Amos S Kinzer and Arthur Morehouse having been found incapacitated for active service by an army retiring board on account of disability incident thereto, their retirement is announced, effective Nov 30, 1930, Capt William J Trebourn proceeded to his home about Nov 30, 1930 to await retirement for the convenience of the government Capt James E Yarbrough is relieved from duties at Walter Reed General Hospital, Washington, D C, he sailed about January 8 for Porto Rico, Capt Ray H Skaggs is relieved from duties at San Juan, P R, effective on completion of present tour of foreign service, and is assigned to duty at Walter Reed General Hospital, Capt William C Williams is assigned to duty at the Army Medical Center, Washington, D C effective on completion of his present tour of foreign service Capt William D North sailed from San Francisco about February 28 for duty in the Panama Canal Department Major William C Porter sailed for San Francisco about February 17 for duty in the Letterman General Hospital, Capt Meyer McC Dougherty, relieved in the Philippine Department and assigned to duty at Letterman General Hospital Presidio of San Francisco Capt Arthur E Brown, relieved at Walter Reed General Hospital, Army Medical Center Washington D C he will sail about May 5 from New York for the Philippine Department, Capt Dean M Walker will sail from San Francisco about April 9 for duty in the Hawaiian Department Major Bonaparte P Norvell, assigned to duty at Miller Field New York, effective on completion of his present tour of foreign service Capt Chester B Leedom will sail from New York about May 26 for duty in the Hawaiian Department Major Leland E Dashiell is assigned to duty at Letterman General Hospital, San Francisco effective on completion of his present tour of foreign service Lieut Comdr Toson O Summers from the naval station, St Thomas V I to the U S Naval Hospital, New York Lieut Clyde M Longstreth from the first brigade, U S Marines, Haiti to the naval air station, Hampton Roads, Va Lieut George W Cooper from the Public Health Service of Haiti to the U S S Sacramento

U S Public Health Service

Asst Surg Edward J Rencke has been relieved from duty on Corst Gurrut Cutter *Sebago* New York, and assigned at marine hospital, New York, Asst Surg Frank F Thwertt, Jr relieved at Ellis Island N Y and assigned in charge at marine hospital, Vineyard Haven Mass Asst Surg Maurice A Roe relieved at Manila, P I, and assigned to duty at marine hospital, San Francisco Asst Surgs Vane M Hoge and Roscoe C Kash, relieved at marine hospital New York and Ellis Island N Y respectively and assigned to duty at the National Institute of Health Washington D C Passed Asst Surg Francis A Ashford relieved at Dublin, Irish Free State, and assigned at Ellis Island, N Y

Vacancies in Government Positions

The U S Civil Service Commission announces that it is in need of eligibles to fill the following medical officer positions
Acting assistant surgeon U S Public Health Service Galveston Texas \$3 800 a year
Acting assistant surgeon qualified in trachoma work U S Public Health Service Ellis Island N Y \$3 000 a year
Acting assistant surgeon for work in pathology U S Public Health Service Ellis Island N Y \$3 000 a year
Medical officer qualified in neuropsychiatry U S Veteran Bureau San Francisco \$3 800 a year
Full information may be obtained by addressing the U S Civil Service Commission, Washington D C

The Milk Problem

In the House of Lords, speaking on a plea made for a national effort to increase the supply of milk by increasing the demand by means of propaganda, Lord Moynihan supported the project with qualifications He said that milk was often contaminated with the result that it caused a number of diseases A hundred people died every day from tuberculosis and \$1 250 000 a day was spent in this country on the treatment of tuberculosis, a large proportion of which was preventable Of the 3,250,000 cows in this country giving milk, more than 1,000 000 were tuberculous What was to be done? If they slaughtered all tuberculous cows, he thought it would be ineffective except as regards the immediate result To immunize the animals would be a matter of great difficulty and uncertainty The problem was to improve the present condition of the milk supply Boiling would destroy all the organisms and was expensive Every drop of milk taken into his house was boiled There were some disadvantages, but the nutritive value, contrary to general opinion, was not diminished However, the vitamins were destroyed, and from the point of view of general consumption the value of the milk was reduced Another method was pasteurization Ninety per cent of the milk in London and Manchester was pasteurized But it was essential that the machinery of pasteurization should be constantly supervised and the greatest possible bacteriologic control exercised at every stage The milk for pasteurization should be as pure as possible There was no doubt that an increased supply of milk was necessary, and it might be well if the government would set up a commission to reconstruct all the knowledge that had been obtained about the problem

Replying for the government, Earl de la Warr, parliamentary secretary to the ministry of agriculture, blamed the medical profession One reason why more clean milk was not produced in this country was the lack of demand If physicians would talk a bit less about dirty milk and do a little more to encourage the buying of the clean milk already on the market, they would be of more use to the nation (Here Lord Moynihan interjected 'We want you to produce pure milk Until that is done we suggest pasteurization') The total production of milk in this country was 1,100 000 000 gallons, of which about 600 000 000 was consumed as liquid milk To bring our consumption up to that of the United States we would require 700 000 000 gallons more than we were producing at present, and if we consumed as much milk a head as was consumed in Sweden we should need a supply of 3,600 000 000 gallons He agreed that our grade designations were unsatisfactory, but the problem was difficult and if he could get general support for a revision he would be only too glad to discuss the matter with the producers

Institution for Surgical Research

The Royal College of Surgeons has made greatly increased provision for surgical research It has accepted the offer of Mr George Buckston Browne a retired genito urinary surgeon, to build and endow an institution of surgical biologic research on an estate at Downe in Kent, which he will present to the college The estate is 16 miles from London and adjoins the western side of Darwin's old home which with its 23 acres of land was presented by the same benefactor to the British Association to be preserved as a museum of Darwin relics and a memorial Mr Browne is willing to endow the new estate with an initial sum of \$270 000 and to add further gifts and legacies until the total amount reaches \$500 000 In a letter to Lord Moynihan, president of the college Mr Browne states

his belief that those who add to the science and art of surgery are among the greatest of all benefactors of the human race and the domesticated animals. He therefore wishes to form an institution in which surgeons, and particularly young surgeons, will have full opportunity to carry out their investigations. The institution will contain three or four laboratories where investigations can be made under the best conditions, or where living animals can be carefully observed and cared for. The detailed work of examining the results will be carried out in the laboratories of the Royal College of Surgeons in London, in connection with which four research scholarships have recently been founded. There is therefore no need to provide pathologic laboratories at Downe. The direction of the preliminary stages of the project is to be entrusted to the conservator of the museum, Sir Arthur Keith. The endowment is intended as a second stage in a scheme for making the college a center of surgical research for the empire as a whole. The president, Lord Moynehan, has taken an active part in the new step. It may be remembered that recently, both in Toronto and in London, he complained that the researches of physiologists were remote from the needs of surgery. No doubt the researches at the Institution of Surgical Research will be designed for the solution of surgical problems.

Enlarged Tonsils, Rickets and Dental Disease

In a second interim report, the Committee of the Board of Education on Adenoids and Enlarged Tonsils discusses the association of these diseases with rickets and dental disease. It finds that extensive enlargement occurs with somewhat greater frequency among children showing signs of rickets, dental disease and hypoplasia than among those who do not show such evidences of vitamin deficiency. The association that has been shown to exist between these conditions and the more extensive adenoid growths, though not dramatic, is too extensive to be regarded as a coincidence. These growths occur frequently among children showing several signs of rickets, in the proportion of about 5 to 3, among children showing extensive caries in the proportion of $4\frac{1}{2}$ to 3, and among those showing severe hypoplasia of the teeth in the proportion of 5 to 3, as compared with children not having such defects. The nature of the relation, however, is not definitely established. The social factors which, taken together, enable the general 'class' of one school to be distinguished from that of another, while they definitely affect the incidence of rickets and caries, have no effect on the incidence of adenoids. This is in harmony with the results of the previous investigation, in which no substantial difference was found in the average extent of the domestic accommodation between the cases and the controls. It seems that the habits of life which predispose to the growth of adenoids are as common in the roomy houses of the comparatively well-to-do as in those of the poorest class.

Archibald Leitch is Dead

Professor Archibald Leitch, director of the research department of the Cancer Hospital, London, has died at the age of 52. Born, June 3, 1878, he graduated in medicine from Glasgow University with distinction. He became house surgeon at the Cancer Hospital, where he decided to take up cancer research. He was appointed assistant to Prof. Lazarus Barlow, director of the Cancer Research Laboratory of the Middlesex Hospital. In 1920 he became director of the research department of the Cancer Hospital. He energetically took up the study of experimental carcinogenesis begun by the Japanese workers Yamagiwa and Ishikawa—the production of cancer by applying tar to the skin of rabbits or mice. He discovered the important fact that when the application was made for a shorter period than that required to produce visible changes in the skin—the method of previous investigators—cancer ultimately developed on the apparently unchanged skin after an interval of a certain number of months in some of the animals. This explained those cases

in which pitch, tar or shale oil workers developed cancer, years after they had taken up another occupation. He studied occupational cancer and tested various materials, including tars, shal oils and lubricating oils, for their carcinogenic properties. In conjunction with Kennaway, he showed that substances which are not carcinogenic can be made so under the influence of high temperature and therefore suggested that there may occur in the body at normal temperatures processes having effects similar to those which are produced by great heat outside the body. He was the editor of the report of the British Empire Cancer Campaign Conference, held in London in 1928, and secretary of the scientific investigation committee, and a member of the grand council and other committees of the campaign.

Vital Statistics The Falling Birth Rate

In the final volume of the registrar-general's statistical review for 1929 just published, the severe epidemic of influenza, which occurred in the early part of the year, is described as the worst since the epidemic of 1918-1919, which followed the war and increased the general mortality by 16 per cent as compared with the previous year. Satisfactory features of the report are reduction from the mortality of diabetes under the age of 55 since the introduction of insulin, and reduction in the mortality from pernicious anemia since the introduction of liver treatment. In 1921 the next inequality was expressed by the ratio of 109 females to 1,000 males, in 1929 the ratio was 1086 to 1,000. The marriage rate (15.8 per thousand of population) was slightly higher than in the previous year and was the highest since 1921. The birth rate (16.3 per thousand) was the lowest ever recorded. The rise in the average age of the population, produced by the constantly falling birth rate, is shown by the fact that the deaths of persons over 70 numbered 389 per 10,000 of population, against 297 in 1911. During 1929, 98 centenarians died, 25 men and 73 women. The striking feature of the report is the maintenance of the marriage rate, which is somewhat above the prewar level notwithstanding the industrial depression. The fall in the birth rate, which is lower than in any other country, with the exception of Sweden, is considered the more serious, since our position in relation to other countries was already low before the war. France, which used to be held up in this country as the great example of the evil of a low birth rate, has a rate about the same as before the war, so that instead of being the lowest the rate is now above that of England, Norway, Sweden and Switzerland.

Traffic in Dangerous Drugs

The committee of the League of Nations on traffic in opium and other dangerous drugs has concluded its report for the session. It regrets that a large number of states have not ratified the convention. Illicit traffic, particularly during 1926-1929, has been found to have been on a more colossal scale than was suspected. A remarkable change was produced at the beginning of 1930 by putting in force the Geneva convention in the remaining European countries other than Turkey, and by bringing under full control the esters of morphine. In the years 1925-1930 some 30 tons of morphine was apparently available for illicit traffic in the form of esters or, possibly, of other drugs. Some 21 tons of morphine appeared to have been exported to the nonmanufacturing countries in excess of medical needs. At the moment when this grave situation appeared to have been remedied by the strict application of the Geneva convention of putting morphine esters under control by several countries, a new danger suddenly appeared in the form of the manufacture on a large scale of morphine and heroin in Turkey, which is not a member of the league or a party to the opium convention. The year 1930 was marked by a striking decrease in the manufacture and export of drugs in some of the chief manufacturing countries of Europe and by a notable decrease in seizures of drugs from these countries but by immense seizures of morphine and heroin, which in a number of cases were known to

have originated in Istanbul. But the committee notes with satisfaction the declaration of the Turkish representative that the Istanbul maritime authorities have received orders to verify exports. However, the committee holds that only the measures of control provided by the Geneva convention, particularly the import certificate system, will make possible the remedy of a state of affairs which is a menace to the whole world.

The Intravenous Use of Germicides

At a joint meeting of the sections of surgery and pathology of the Royal Society of Medicine, Mr. Zachary Cope opened an important discussion on the intravenous use of germicides. He included under germicides any substance that would kill germs, either directly when brought into contact with them or indirectly by unfavorably affecting their environment in the body. To be of value a germicide should have only a small toxic action on the body in the dose employed. Germicidal efficacy might be estimated in the test tube or in animals. The supreme test is the clinical effect in man. For example, arsphenamine is ten times as lethal to the Leishman-Donovan body in vitro as antimony and potassium tartrate but is no good for leishmaniasis, whereas antimony and potassium tartrate is a specific. Intravenous therapy has been more successful with protozoa than with bacteria, as shown in syphilis, frambesia, relapsing fever, dysentery and malaria. According to Professor Fleming, none of the ordinary antiseptics have a bactericidal effect in the blood stream. Intravenous arsphenamine has proved effectual in malignant pustule but useless for the septicemic form of anthrax. The treatment of bacterial diseases by intravenous injection is not on a sound foundation. Laboratory tests are doubtful and clinical results conflicting. Ethylhydrocupreine in pneumonia and 'Sinocrysin' in tuberculosis have proved disappointing and dangerous. For severe septic infections no reliable drug has been found. A good trial has been given both to mercurochrome-220 soluble and to the aniline dyes, but no one can continue to believe that antiseptics can have any direct effect on organisms in the blood stream except in a strength that would be poisonous to the patient. Any effect due to them must be indirect. Young of Baltimore is an enthusiast for mercurochrome, but others who have given it a fair trial have had nothing but failures.

Professor Fleming, bacteriologist in the inoculation department of St. Mary's Hospital, said that the bactericidal power of the blood was centered in the leukocytes, but that germicides damaged these more than they damaged bacteria. This applied to eosin, mercurochrome, flavine, gentian violet and 'Sinocrysin'. Although these results held out no hope of exerting a direct bactericidal action, high dilutions of arsphenamine, not in themselves bactericidal, appeared to increase the bactericidal power of the blood for *Streptococcus pyogenes*. This action he was unable to explain.

Outbreak of Paratyphoid Due to Infected Milk

An outbreak of paratyphoid (B) fever has occurred in Essex, near the eastern border of London. Between February 1 and 14 there were 172 cases. The illnesses in many cases were severe but only four cases proved fatal. Inquiries made by the ministry of health in conjunction with the local health officers appear to show that the outbreak was due to infection of the milk supply on a particular farm. The infections seem to have been introduced by one of the employees who, unknown to himself, was suffering from a mild attack of paratyphoid fever while at work and handling the milk for distribution. For several days milk thus infected was consumed by a considerable number of persons in the surrounding districts. At the farm in question all those suspected of possibly carrying the infection, including the man mentioned, have been removed to a hospital. The distribution of milk from the farm was stopped for the time necessary for thorough disinfection of the premises and utensils.

Feb. 4, 1931

The Excess of Physicians

Dr. Cibrie, general secretary of the Confederation des syndicats médicaux français, has published an article describing conditions that make the practice of medicine in France more difficult and emphasizing that it is time to make serious efforts to divert young men from this difficult career. He points out that the minimal expenditure for the long years of study, for the practitioner of the most modest ambitions, is \$4,400 and that the amount reaches more than twice that sum if the graduate desires to prolong his studies and to take the various competitive examinations that lead to the modest positions in the medical schools or to posts on the medical staffs of hospitals. According to the census of 1928 there were 28,380 practicing physicians in France as compared with 16,480 in 1901, or an increase of 12,900 physicians for a population that has increased, during the interval, only by two million inhabitants. The number of students of medicine has increased from 8,779 in 1911 to 14,574 in 1929, and the trend is still upward. A committee has been appointed by the confederation to study the question of the excess of physicians and to devise the best means of remedying it. The committee, on which five professors are serving, addressed a circular letter to the professors of the medical schools in France. Eighty-six replies were received, which were almost unanimous in support of the following measures as a means of solving the problem. 1. For admission to the study of medicine, in addition to preparatory work in the sciences, preparatory courses in both Greek and Latin should be required. 2. Instruction in the natural sciences, physics and chemistry, the so-called premedical sciences, which is now given in the facultés des sciences, should be assigned to the facultés de médecine. 3. After the first months of medical studies properly so called, students who are manifestly unsuited for the study of medicine should be definitively eliminated. 4. Certain methods of instruction should be modified so as to make the student realize during his medical course, the principal performances of current medical practice. 5. The examinations should be made more severe and should be given twice a year on fixed dates with one or two written tests that do not bear the name of the student and that are submitted to a board of examiners not previously announced. These methods were applied to the schools of law, which were likewise overcrowded, and the number of students was reduced by 50 per cent with the result that some students who failed to secure admission to the schools of law were diverted to the schools of medicine. Finally, the committee demanded the prompt consideration of the bill filed in the chamber of deputies by Dr. Ambruster which provides for the elimination of the special favors that foreign students and physicians at present enjoy in the form of *équivalences* or advanced credits for examinations taken in their own countries together with the requirement that every foreign physician under 30 years of age desiring to practice medicine regularly in France be required to become naturalized when such physician has come from a country in which naturalization is required of French physicians desirous of practicing in that country. The *ex-favores* have been liberally accorded to foreign students in the past because it was assumed that they would return to their own countries to practice medicine after completing their studies in France. However, it has been observed that nearly all such foreigners, after securing their diploma under conditions that are not as severe as are required of French citizens settling in France. The percentage of foreign students in the facultés françaises has risen from 12 per cent in 1900 to 25 per cent in 1929 and increases the number of French physicians admitted to practice in foreign countries is almost nil. Furthermore, one cannot fail to recognize that the *ex-favores* physicians who are locating in France with the exception of a

few laboratory specialists are not of the best quality. In Paris, of ten medical scandals in which physicians are summoned before the courts, seven concern foreign physicians.

Responsibility of the Government for Misdemeanors of Mental Patients

The Conseil d'état rendered recently a decision that may have in the future serious consequences for its decisions have always the character of finality, as those of the supreme court, and in interpretations of existing laws establish the jurisprudence until some new law is enacted. A dangerous mental patient had been interned in the departmental psychopathic hospital of Basses-Alpes. The chief physician after a time, considered him cured and dismissed him. But the patient presented new signs of hyperexcitation and uttered grave threats against one of his neighbors. The mayor of the village informed the prefect of the department and requested that the patient be interned again. The prefect did not comply with the request of the mayor and one day the patient killed his neighbor. The widow and the daughter of the victim served notice on the government that they held it responsible for the death and claimed compensation. The minister of the interior did not reply but contented himself with transmitting the papers to the minister of public health, who also failed to reply considering that the minister of the interior was alone responsible for the acts of his prefects. The mother and daughter addressed themselves therefore to the Conseil d'état, which approved their claims and declared that the minister of the interior was responsible the mayor having taken promptly all the steps required by the regulations. The government will accordingly pay \$800 to the daughter of the victim and an annuity of \$120 to the widow during her lifetime. This decision is important. There are in the small villages of the rural districts many mental patients whom the mayor in spite of the recommendations of physicians, refuses to commit to a psychopathic hospital when they are indigent since, in that case, the cost of their stay in the hospital falls on their municipality. The physicians deliver to the mayor certificates of commitment but the mayors do not order the internment so long as the patient shows no signs of becoming violent. In the case cited, in which the Conseil d'état rendered a decision the mayor had done his duty. The prefect had failed to do his duty and the state is responsible for the acts of its prefects. As yet the responsibility of the chief physician of the hospital who had dismissed a mental patient who was still dangerous has not been brought up. That is however a frequent occurrence when the hospitals are crowded and room must be found for new patients. Some day perhaps a case will be brought before the courts to decide the question of the secondary responsibility of the government for the acts of the medical director of a public establishment. The tendency of present day legislation is to grant an individual damages for injuries that he suffers without being personally at fault.

Protection Against Toxic Gases

Before the Academy of Sciences Prof Charles Richet presented recently a communication from Mr Marseille in which the author brought out that no filtering apparatus will protect the wearer against the great variety of toxic gases at present known (there are more than a thousand). The only protection would consist in having the subject breathe in an elastic vessel isolated from the atmosphere in which the carbon dioxide is absorbed by an alkali and in which the oxygen is constantly renewed. The most toxic gases will then have no effect. Mr Marseille demonstrated an apparatus constructed on this principle.

Free Instruction for Abnormal Children

A curious case was tried recently before the tribunal de la Seine. There is in Paris a national institute for the education of deaf-mutes which is more than a hundred years old. The parents of the pupils are compelled to pay for the cost of their

education especially as they receive also board and lodging. This year, a number of parents got together and decided to refuse to pay the cost of the board of the pupils assigning as their reason that the law of June 16, 1881, provided for free compulsory education. The court decided naturally against the parents, for the parents are under no compulsion to place their deaf-mute in the Institut national des sourds-muets, they may keep him at home or they may place him in any public or private institution—whether free or subject to charges. The court merely expressed its regrets that there are not as yet a sufficient number of free institutions in which deaf and dumb children are fitted to associate with their fellow citizens on a normal intellectual basis. But the court declared that it was impossible for it to give to the law pertaining to free compulsory education an interpretation that was not intended.

Death of Prof Georges Weiss

The death of Prof Georges Weiss, honorary dean of the Faculté de médecine de Strasbourg, at the age of 72, was announced. Born at Bischwiller, Alsace in 1858, he left his home after the annexation of Alsace by Germany. He entered the Ecole polytechnique de Paris and obtained the degree of engineer of bridges and highways. He soon abandoned this career to take up medical studies and became associate professor and later professor of medical physics at the Faculté de médecine de Paris, in 1901 succeeding Professor Gariel. In 1907 he was chosen member of the Academy of Medicine and in 1918 he became dean of the Faculté de médecine de Strasbourg. His publications dealt chiefly with physiology, optics and electricity in relation to medicine.

The Down-Swing of a Charlatan

Zeileis the charlatan of Upper Austria, was widely known for his high frequency treatment that is to say, he held a high frequency tube aloft in his hand, the rays from which he held in the shortest space of time, many gullible followers. The maneuvers that he went through do not deserve at all the name of treatment but consisted merely in the waving of the sputtering tube over the heads of his patients as they marched past him. Nevertheless hotels sprang up in Zeileis small village almost over night while unheard-of crowds of patients flocked to see him. In spite of the existence of a law against charlatanism, the governor of the province made no move to check the shameful spectacle and it was whispered that the whole region round about drew too much profit from the pockets of Zeileis followers. Zeileis institutes were opened everywhere—in Austria, Czechoslovakia and Germany. Even physicians became directors of such institutes (this fact is referred to among the nature doctors and among the people as 'the crisis in medicine'). Fortunately, however, the "collapsus" failed, for the most part to make much money out of their ventures, for, it was alleged real benefit from the Zeileis treatment could come only from the Upper Austrian village of Gallsbach. An attempt was made—as so often—to combat the fraud by the publication of scientific articles but of course without success for the readers of the scientific articles are not the persons who go to the charlatan. These things must be viewed with something of the mind of the fatalist. Sooner or later the swindle will run its course. And, judging from newspaper accounts so it is with this fraud. As the zenith of prosperity was reached some time ago now the numerous hotels and shelters that sprang up are all empty. It is said that forty-two such buildings have gone into the hands of a receiver and are to be sold at auction. Apparently the down-swing began with the typhoid epidemic last summer. But the chief blow doubtless came from the many suits brought by the cured

patients before the Vienna courts. The persons whose health had been injured (not only by fraudulent treatment but still more by the loss of valuable time during which they might have had proper treatment) formed a committee to bring against Zeileis a joint suit for damages. Nothing is heard now of the Zeileis institutes in the various cities. What and who will be next?

The Number of Illegitimate Births

The absolute annual number of illegitimate births in Germany is more than 12 per cent lower than during the prewar period, but the proportion of illegitimate births to the total number of births in Germany is still 20 per cent higher than during the prewar period. The number of illegitimate births per thousand unmarried women is today less than during the prewar period and is constantly declining, in spite of the present large excess of women over men, in Germany. The illegitimate births are decreasing at nearly the same rate as the legitimate births, whereas, in many other countries, they are increasing. In Chile and Cuba the number of illegitimate children is very high, in Italy, England, the Netherlands, Switzerland and Norway, the percentage of illegitimate births is on the contrary, extremely low, in Germany and Austria, France, Ireland, Hungary, Sweden, Denmark and Spain, it is about the average for Europe and for years has not varied much.

New Forms of Gold Treatment

Injection therapy with gold has the disadvantage that occasionally, on account of too great toxicity of the compounds employed, undesirable secondary effects, more particularly exanthems, appear. It is, therefore, an important advance that now the action of this therapeutic remedy when administered orally has become known. Gold develops a catalytic action as one of the so called heavy metals. It accelerates oxidation in animal experiments and produces chemical changes. Freund, an assistant physician in the v. Bergmann Charitéklinik treated as he reported at a meeting of the Berliner Medizinische Gesellschaft, orally chronic infectious arthritis and chronic polyarthritis, in which a pathogenic connection with previous infections was to be assumed. Cases were selected more particularly that were refractory to treatment with salicylic acid, irritants and heat. During gold therapy no supporting measures are to be employed. There were a number of failures but nevertheless such a large number of controlled successes that already oral therapy as a method of treatment in general practice can be recommended, especially as no untoward instances of importance were observed. Occasionally during the beginning of the treatment focal reactions taking the form of increased pains in the joints, with some diarrhea appeared but disappeared again without any change in the mode of treatment. Film pictures were shown of patients who for a long time had been unable to work, some of them having been confined to bed. They show great improvement in the mobility of the joints while some have learned to walk again without a cane and have become able to work. As a rule the gold treatment was begun after fourteen days' stay in the hospital and always as the sole mode of treatment. The point of attack of the gold is the mesenchymal apparatus. In contrast with irritants by means of which a marked and sudden change of reactivity is brought about this preparation acts gradually by the oral route. The sulphur is not split off from these compounds.

A New Tuberculosis Hospital

The government hospitals and the university clinics have so few beds for hospital patients that they do not play any considerable part in the crusade against tuberculosis nor do they furnish any regular and adequate material for the clinical instruction of students. There are however a few tuberculosis hospitals in Germany, some of which have a large number of beds (the Sommerfeld Krankenhaus 400 beds, the newly erected Bechitz Krankenhaus 1 200 bed) but which have no connection

with the universities so that their patients cannot be utilized for scientific instruction. It is the merit of Albert Fraenkel, the Nestor of the tuberculosis specialists, that through the reconstruction of the 'Rohrbacher Schlosschen' near Heidelberg an institution has been created which makes possible the care of tuberculosis patients of all stages, which has likewise an aid fund, and which combines the practical treatment of tuberculosis patients with scientific research and clinical instruction. Fraenkel is doubtless correct in his assertion that the health centers alone cannot be expected to do adequate work in the crusade against tuberculosis. For the effective combating of tuberculosis internment of the advanced cases is needed and especially of the bacillus carriers, secondly a system of ferreting out early cases and the supervision of tuberculous patients by the physician during the remainder of their lives. The first demand is met by the tuberculosis hospital, the second by the welfare aid system. Only through close cooperation of the tuberculosis hospital and the welfare aid system is a crusade against tuberculosis that promises success at all possible. The Rohrbacher Schlosschen is a beautiful, well preserved structure and in its reconstructed form is a modern tuberculosis hospital with accommodations for about a hundred patients. Owing to the fact that not more than three patients occupy one room (there are also many single rooms), the hospital has more the character of a sanatorium, which is of the greatest importance for the mental well being of the patient. The institution has a close connection with the institutes of the University of Heidelberg.

Neuroses of Genital Origin

A recent session of the Verein für innere Medizin held in Berlin was devoted to the memory of its deceased honorary chairman Prof. Paul Fürbringer. The chairman, Professor His, discussed before the assembly the development of the theory of genital neuroses in males, a subject studied by Fürbringer for half a century. The disorder is mentioned by Hippocrates, although the modern treatment began in France in the fore part of the preceding century. Fürbringer's researches have great value owing to the detailed critical description of the symptoms. But with the interpretation it is different. From this angle modern research on the hormones and on the psychologic aspects of the subject have brought great progress. Privatdozent Dr. Kronfeld reported on these phases. He emphasized especially the value of studies on the personality of the subject and of the psychoanalytic method. The wavering self valuation of these patients, which points to an abnormal relation between the ego and the natural instincts as the nucleus of the neurosis can be pregnantly understood psychoanalytically from the history of the superego conceptions and the various phases in the development of the libido. From this fact it follows that psychotherapy is of greater value than endocrine treatment.

Medical Education in Australia

Owing to the many new medical subjects that require special attention it is becoming extraordinarily difficult to include in the present medical course of six years everything which should be taught. Was the opinion of Sir Richard Stawell who delivered the third Hildorf oration at the institute of anatomy at Canberra taking as his subject 'The Establishment of a Medical School and the Development of Medical Education.'

When medical education was first commenced at the Melbourne University the university council had determined that the curriculum for the degree of bachelor of medicine (M.P.) should consist of a five years course. This was longer by a year than any systematic course of medical education in the United Kingdom and Ireland. The university at the time this curriculum was drawn up was bitterly attacked but thirty

years later the British Medical Council insisted on the minimum of a five years' course in the United Kingdom.

Sir Richard Stawell traced the development of medicine in Australia and the changes that had been made in the university curriculums to keep pace with it. Experience in the United States, Great Britain and Germany had firmly convinced Sir Richard that the average Australian medical practitioner had a high standard of efficiency when compared with the standard of medical practice in other countries. He ascribed this to the better teaching in hospitals, where the senior students engaged in responsible work under proper control.

The Halford oration which was endowed by relatives of the late George Halford, founder of the first chair of medicine in the Melbourne University, is given each year.

Vital Statistics

At the end of 1929 the population of Australia reached the total of 6,414,372. The rate of growth during 1929 was 1.22 per cent and for the ten years 1.92 per cent which is probably the highest rate of increase in the world. Excess of births over deaths contributed 70.5 per cent of the total increase and net immigration 29.5 per cent. The density of population of Australia is only 2.16 persons per square mile and varies from one person per hundred square miles in the Northern Territory to 20.22 persons per square mile in Victoria.

The birth rate for 1929 20.31 per thousand of population, was the lowest ever recorded. Compared with many other countries the Australian rate is low but it is fortunately accompanied by a low death rate giving a rate of natural increase that is equaled in few countries. Extramural births numbered 4.70 per cent of all births registered. The proportion of multiple births is one case of twins in every 98 confinements and one of triplets in 14,242 confinements. The average number of children per mother was 2.96 against 2.99 in 1928.

During the year 60,857 deaths were registered corresponding to a rate of 9.55 per thousand of the population. This rate was slightly above the average of the previous five years but nevertheless compares most favorably with other countries. The principal causes of death were heart diseases, 15.3 per cent, cancer, 10.3 per cent, violence, 6.0 per cent, cerebral hemorrhage, 5.8 per cent, tuberculosis, 5.7 per cent, nephritis 5.6 per cent, pneumonia, 4.9 per cent. The number of deaths in childbirth was 5.1 per thousand children born. The infant mortality rate for Australia (deaths of children under the age of 12 months) per thousand children born was 51. This rate is the lowest ever recorded in Australia and is, with the exception of New Zealand, the lowest in the world. The rate for New Zealand is 34.

Health Week

The crystallizing of health education by means of a health week was carried out this year during the middle of November. This activity found its fullest expression in Melbourne and Sydney. In Melbourne there was a celebration of the fact that during last year the infant mortality rate there had been the lowest ever recorded. Health week was conducted under the auspices of the Health Association of Victoria. Mental hygiene was made a feature of the education but cleanliness, good living, wholesome food and effective control of infectious diseases were the general topics brought to the notice of the public.

Hospital Dietetics

As a result of the interest of Dr. Malcolm McEachern, who visited Australia in 1926, the authorities of the Alfred Hospital in Melbourne were enabled early this year to secure the services for twelve months of Miss Mabel G. Flanley, graduate in home economics of the University at Washington who took her dietitian's training at the Peter Bent Brigham Hospital, Boston. Commencing with a survey of hospital needs and conditions in Melbourne, Miss Flanley has impressed the hospital authorities with the increased efficiency and economy attendant

on the application of dietetic science to the feeding of hospital patients. Lectures to diabetic patients have been given regularly. By the standardization of methods of preparation of food, by approximating requisitions more closely to requirements, and by eliminating avoidable waste, a saving to the hospital (350 beds) of £268 during the last six months has been effected.

The dietitian's work has proved of such benefit that she has been asked to extend her visit. Her advice on the planning and equipment of new dietetic departments has been sought by the architects of four hospitals at present under construction in Victoria.

The new kitchen at the Alfred Hospital is to be used as a teaching laboratory for hospital dietitians. It is intended to have two students and two assistants working under the director. The training period will be six months and among applicants for students preference will be given to those having the degree of bachelor of science or those who have taken a course in domestic economy and institutional management.

Poliomyelitis in Victoria

For the past four years, the health department of the Melbourne city council has been conducting a campaign against infantile paralysis. Recently, the other city and municipal councils have shared the expense of the campaign. Under the control of a medical director, human serum has been obtained from recovered patients placed in ampules at the Commonwealth Serum Laboratories and held in cold storage at Melbourne. Lately it has also been stocked at twelve centers in the country districts of the state. The total cost of the campaign activities last year was £1,000, of which the Victorian government contributed half. In many instances, prompt diagnosis and early treatment had minimized the extent of the paralysis and the campaign will be continued. Action is being taken in Sydney to provide similar serum treatment.

The "Outback Child" Problem

In New South Wales and Queensland the bulk of the population live along the seaboard, and the inland areas (known locally as the far west) are sparsely populated, the land being used mainly for sheep and cattle grazing. The problem of providing medical and dental services for the children of these areas is one that is exercising medical administrators and charitable associations in Australia. In the far west the medical situation is further complicated by a high incidence of trachoma. Dust, flies and malnutrition are contributing causes to this high incidence.

In providing medical services for these children, school medical inspection, the traveling dental clinic, the child welfare clinic, the Queensland ambulance service (considered to be one of the most efficient in the world), various inland missions, the flying doctor and the bush nursing society all do their magnificent part but even so, limitations of time, distance and finance make the problem inherently difficult. The dental clinics of the education department in New South Wales, for instance, are continually traveling and yet they can visit each place only once every three years. Subsidiary methods of providing services necessitate bringing the children to the centers of population.

In Queensland the country women's association has organized seaside homes for the accommodation of batches of outback children. The education department of Queensland has established an ophthalmic hostel for the concurrent general education and treatment of the worst cases of trachoma. In New South Wales is a movement called the "far west children's health scheme" organized by the national council of women. The first effort was a seaside camp where special facilities were provided for medical and dental treatment, such as removal of tonsils and dental attention. Every child is chosen from among hundreds of needy cases by a physician or

a schoolmaster. The child must not only be in need of treatment but must also belong to parents who could not possibly procure help in any other way.

A more recent development of the far west children's health scheme is the appointment of a skilled orthopedic surgeon to travel to country centers to examine and advise on the possibilities of treatment of crippled children who would be selected and assembled by local physicians or schoolmasters. The cases suitable for treatment would then be sent to the state capital.

One of the most recent developments is the airplane ambulance. By this means patients can be transported long distances with comfort, one such patient, with a fractured spine was brought 1,000 miles from central Queensland to the state capital for operation. In some of the far western towns the local physicians, when bad weather makes the roads impassable do their country rounds by airplane taxi at a cost of 2 shillings (40 cents) a mile.

JAPAN

(From Our Regular Correspondent)

Feb 2, 1931

Fewer Women than Men in Japan

The general census taken Oct. 1, 1930, in this country was successful and the result was published by the government December 8. The population of Japan proper is 64,447,724 comprising 32,388,369 males and 32,059,355 females, which is nearly double the population in 1872, fifty-nine years ago. According to the Committee for the Investigation of Population and Food Problems, it is estimated that the population of Japan proper will grow to almost 90,340,000 in the next thirty years. The committee, which has handed the draft of its report to the prime minister, points out (1) the necessity of establishing medical consultations for marriages, births and birth control, and (2) the necessity of investigation and research on the facilities of Japan from a eugenic point of view. It also proposed the organization of a permanent committee for the purpose. As to the population, it is strange to find that the number of males exceeds by 329,014 the number of females, 101 males to 100 females. Tokyo has the highest ratio of males to females, 111.9 to 100, next comes Hokkaido, 109.3 then Osaka 108.9. In large cities and the mining and planting districts the number of males is greater, while females are more numerous in places with many spinning factories. The smaller number of females is said to be due to the fact that many females die young. Dr. T. Nagai, specialist on problems of population, has published his opinion that Japanese mothers are apt to have another baby soon after they have lost their children. On this occasion of the census, he hopes, the people at large will seriously consider the problem of population.

The Birth Control Union

The organization of the birth control union in which Dr. Miyajima, member of the Tokyo municipal assembly, has long taken the initiative has been realized at last. About 200 members met, January 17 for the first time in the Tokyo Physicians Building at Kanda, Tokyo, under the presidency of Baroness Ishimoto. They decided that 1. The union shall join in and be affiliated with the International Birth Control Union. 2. The union shall investigate various studies on birth control and make reports of them. 3. The union shall publish opinions in defense against irrational attacks and opinions attacking birth control methods or establishments which are found to be unscientific.

Rockefeller Offers Japan a School of Hygiene and Public Health

Dr. Heiser of the Rockefeller Foundation arrived November 2 at Yokohama on his way to China. He visited Tokyo to see Mr. Adachi, home minister. Mr. Akagi, chief of the sanitary bureau and Dr. Teusler, chief of St. Luke's International Hospital concerning the establishment of a new school of hygiene and public health in Tokyo. After the arrival of Dr. Grand

of the same foundation, whose mission was to choose scholarships for young men of medical science or engineering at the Rockefeller Institute in America, the two negotiated with Dr. Miyajima and then officially offered to our government a large sum of money annually for the establishment of the new school.

The home minister, who was glad to receive the generous offer, nominated the following special committee for organization: November 9 advisers, Dr. Hayashi, dean of the medical department of the Tokyo Imperial University, Dr. Kitajima, dean of the Keio Medical College, and Dr. Teusler, chief of St. Luke's International Hospital, chairman. Mr. Akagi, chief of the sanitary bureau, commissioners Drs. Nagayo and Miyagawa of the Imperial University of Tokyo and the government institute for the study of infectious diseases, Drs. Miyajima and Hatai of the Keio Medical College and the Kitasato Institute, Dr. Sato of St. Luke's International Hospital, and Drs. Kusama and Noheji of the sanitary bureau of the home ministry. They met in the home ministry several times beginning December 4 and on the 11th, Dr. Grand, who had come back from China, attended the meeting. General plans were made as follows: the expenditure for the school building \$5,000,000, the school term two years, qualifications to enter the school, qualified physicians, obligations of the graduates, to go out into practical work in factories and schools, other establishments, to organize health centers in cities and villages. On the evening of the 12th, the Rockefeller Institution Alumni Association in Tokyo gave a dinner in honor of Dr. Grand, who was going again to China on the 14th.

Women's Pharmaceutic Colleges Licensed

Legal licenses have been given by the educational department to the Kyoritsu Women's Pharmaceutic College, which opened in April, 1930, the Tokyo Women's Pharmaceutic College, which opened in November, 1930 and the Showa Women's Pharmaceutic College, which opened in November, 1930.

Examination for Licensing Medical Practitioners

In the state examination held for the medical practitioners toward the end of last year (1930), the following four foreign physicians were licensed out of twenty-seven candidates for medical practice and twenty-eight for pharmaceutic physicians and pharmacutists: Dr. T. F. Rowy, United States, Dr. H. E. Boles, United States, and Dr. T. Schmidt, Germany, physician. Dr. Visura Nias, India. The examination, which used to be held in July and December, is now held once a year.

Fellows of the League of Nations

On the recommendation of Dr. Tsurumi, the Health Section of the League of Nations has granted fellowships to three Japanese scholars. They left here at the end of 1930 to stay in Geneva for two or three years. Dr. Humano chiefly will investigate the disposal of sewage and improvement in villages. Dr. Yotai will pursue studies in bacteriology, and Dr. Abe in social hygiene.

Meetings of Societies

The Japan Racial Hygiene Society, which was long promoted chiefly by Dr. Nagai, professor of eugenics in the medical department of the Tokyo Imperial University, has been organized under the presidency of Viscount Toki. The opening ceremony was held in the Municipal Hall at Hibuya Park November 30. After the addresses of the minister of home and education, lectures were given by Dr. Miyake and five other celebrated men of sciences.

The Tokyo Prefectural Sanitary Authorities gave lectures to school sanitarians in towns in the neighborhood of Tokyo in December, on prevention of infectious diseases in schools and the nursing of school children. The Kumamoto Medical College also gave a course of lectures on school hygiene for four days, December 8-11, about 400 school masters, teachers and school nurses attended.

Personal Items

Dr C Yokote, professor of hygienics in the Tokyo Imperial University, has retired having reached the age limit. Dr Mochizuki died at the age of 72, November 29. He was formerly principal of the Kyoto Medical College. Dr Inoue, professor of anatomy to the Tokyo Imperial University, who left May 1 last year to attend the hundred and twenty-fifth anniversary of the Krasa University, Krasn, Russia, returned to Tokyo October 3. He is reported to have been treated as a guest of the nation in Russia and had the honor to make an address before the students of the university and the citizens at the reception May 15. On the day of the celebration he delivered a lecture on "Development of the Palate." After that he went to Amsterdam to attend the third International Anatomy Meeting, August 4, as delegate from Japan.

NETHERLANDS

Government Health Insurance

The law pertaining to sickness, as revised under date of June 14, 1929 provides for the granting of cash benefits in case of sickness and constitutes a form of compulsory insurance. A person insured under this law is entitled, in case of sickness, to sick benefits, which may not exceed 8 florins (\$3.20) a day. However, an insured person has no claim to sick benefits if (1) the sickness is the result of an accident covered by the law pertaining to accidents, or (2) the sickness is the result of intention, a misdemeanor or immorality. Married women during pregnancy and confinement are regarded as patients. The law does not define the term 'sickness' but considers that sickness obtains if a person is unable to work and requires medical treatment.

In Memory of Prof Dr Christiaan Eijkman

Prof Dr Christiaan Eijkman, Nobel prize winner in physiology and medicine, passed away at Amsterdam, November 5. He was appointed health officer following the publication of his treatise on "Polarization in the Nerves," and soon afterward undertook his first voyage to the East Indies. On a second voyage he was a member of the commission on beriberi, which was under the direction of Pelchering and Winkler. On his return from that voyage he was appointed professor of hygiene, medical police control and legal medicine at the University of Utrecht. In his articles he dealt with a great number of subjects pertaining to colonial medicine. He pointed out that, in the East Indies, Europeans do not suffer from anemia, their temperature is not increased and their nutritive and physiologic exchanges are the same as here in Europe and do not differ in any respect from the manifestations in the natives. It is superfluous to do more than mention the enormous influence of his work on beriberi to him belongs the honor of having created the science of vitamins. Aside from his eminence in physiology, Professor Eijkman showed himself to be a no less remarkable bacteriologist to cite his researches on the functions of bacteria and on the conditions of growth and death of ferments, which interested him more than the study of pathogenic bacteria.

Malaria in the Netherlands

The report of the malaria commission of the council of health for the years 1927-1928 notes that the work of the commission has shed light on the autumnal infections that are highly latent. The investigations of Swellengrebel, during the period 1920-1923, on the natural infection of *Anopheles* established that it is encountered in autumn in *Anopheles* found in houses. This had the effect of giving different directions to the crusade against malaria by substituting for the destruction of *Anopheles* the destruction of the mosquitoes in the houses, especially during the autumn season.

Dr P C Korteweg studied the frequency of recurrences the following year in persons who were infected with malaria before, and also in those who were infected after, September 1. Of 1,108 persons infected before September 1, there was 128 per cent of recurrences during the following year. In 170 who were infected after September 1, there was 40.6 per cent of recurrences. Experiments were made with marked mosquitoes, which reveal that *Anopheles* may be recovered 3,000 meters from the point where they were released.

According to the researches of Van Thiel, Van Swellengrebel and De Buck it seems likely that two species must be incriminated that can be distinguished only by the length of their wings. The two species may become infected with malaria, but it may be noted that it is *Anopheles* with short wings that produces the infection of the autumn season, and since the autumnal infections prepare the way for the worst infections of the following spring, the problem of anophelism without malaria is partly explained. As to *Anopheles* with short wings, the brackish water appears to attract them more than the other species.

Increase in Height of Hollanders

In the review *Mensch en Maatschappij*, Prof J P Van den Broek publishes an article concerning the increase in the height of Hollanders. He concludes from his study of statistics that: 1 The average height of man in the Netherlands is 1.72 meter. 2 After Sweden, Norway and Scotland, the height of man in the Netherlands is the greatest of any country. 3 The average height is greatest in Friesland, Groningen and northern Netherlands, and the least in Limburg and North Brabant. 4 The increase in height is a world wide phenomenon. It is sometimes said that the increase is due to the greater wealth and comfort that have resulted from the absence of alcoholism, but to this assumption certain objections may be raised. This increase in growth has been going on for sixty years. The increase in all parts of the Netherlands is uniform, and the same increase is noted outside the Netherlands.

Honorary Degrees Conferred

Prof V Zeeman has been awarded the degree of doctor honoris causa by the Faculté des sciences of the University of Paris, and Prof H Zwaardemaker has received the same honorary title from the Faculté de médecine of the same institution. The doctorate honoris causa of the Sorbonne was conferred at this time on five scientists—one for each of the five faculties. That two of the five awards should have fallen to the Netherlands is a source of gratification. France is a country of broad general views, of clear thinking and precise forms. For that reason, a distinction of this kind has a peculiar significance.

Blood Transfusion Service Organized

A blood transfusion service has been organized at Rotterdam by the Red Cross. Any physician may send in an urgent request for a blood donor. The creation of the service has been widely advertised in order that it may be of aid when one searches in vain for a suitable donor among the members of the family, the friends and the acquaintances of the patient.

Marriages

MORTIMER BYRON DOWNER JR Woodstock N Y, to Miss Carol Sophia Hallstrom of Flushing January 24.

WILLIAM JAMES FAGALY, Lawrenceburg, Ind, to Miss Dorothy Rae Wheeler in East Warsaw, January 15.

WILLIAMSON ZIGLER BRADFORD to Miss Mary Coley Spier, both of Charlotte N C, January 6.

ROBERT M WARE to Miss Sarah Pollard both of Fitzgerald Ga in Lale City Fla January 6.

BERT M BREWSTER Fieldon Ill, to Mrs Beatrice Johnson in St Louis January 16.

Deaths

Edward Eliot Harris * New York Medical Department of the University of the City of New York, 1880, member of the House of Delegates of the American Medical Association 1902-1906, 1917-1927, for many years speaker of the house of delegates of the Medical Society of the State of New York, professor of physiology and hygiene in Rutgers College, 1881-1885, assistant to the chair of physiology and histology, 1881-1883, instructor in the laboratory of biology and pathology 1882-1884, at his alma mater, inspector for contagious diseases New York Board of Health, 1882-1886, on the staff of the New York Children's Hospital, Randall's Island, aged 74, died, February 25

Ernest Catron Wheeler * Tacoma Wash., Chicago Homeopathic Medical College, 1897 Rush Medical College Chicago, 1899 member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Otolaryngological Society, served during the World War aged 58 died January 21 in the Tacoma General Hospital, of paralytic ileus, following an operation for obstruction of the small intestine

Samuel T Earle, Jr * Baltimore University of Maryland School of Medicine Baltimore, 1870, formerly professor of physiology and diseases of the rectum, Baltimore Medical College, member of the American College of Surgeons past president of the American Proctologic Society and the Medical and Chirurgical Faculty of Maryland aged 82 died suddenly February 19, in the Union Memorial Hospital, of angina pectoris

Tinsley Brown * Hamilton Mo., Missouri Medical College, St. Louis 1876 past president of the Missouri State Medical Association, secretary and formerly mayor of Hamilton postmaster and member of the school board past president of the Caldwell County Medical Society, aged 81, died, February 9 of cerebral hemorrhage

Frederick Albert Bardwell, Oteen, N. C. New York Homeopathic Medical College and Hospital 1893 Harvard University Medical School Boston, 1901 member of the Massachusetts Medical Society on the staff of the U. S. Veterans' Hospital number 60, aged 66, died, February 15 of coronary thrombosis

Guy Harrison McFall, Detroit Detroit College of Medicine 1899 assistant professor of rhinology laryngology and otology at his alma mater on the staffs of the Herman Kiefer Hospital and the Children's Free Hospital aged 54, died, February 20 in the Jennings Hospital, of pneumonia

George W Brose, York, Pa. Hahnemann Medical College and Hospital of Philadelphia 1891 member of the Medical Society of the State of Pennsylvania, on the staff of the Danville (Pa.) State Hospital aged 68, died February 6 of hypertrophy of the prostate and chronic nephritis

Frederick Charles Keck, San Francisco Cooper Medical College, San Francisco 1894 member of the California Medical Association formerly professor of electrotherapeutics College of Physicians and Surgeons of San Francisco aged 66, died, February 16 of pneumonia

Frank Raymond Stubbs * Newton Mass. Harvard University Medical School, Boston 1897 formerly instructor of histology at his alma mater aged 59 on the staff of the Newton Hospital where he died, February 9 of cardiac decompensation and pulmonary edema

Charles Edward Abbott, Andover Mass. Harvard University Medical School, Boston 1881 member of the Massachusetts Medical Society formerly member of the state legislature aged 74 died January 25, of arteriosclerosis and cerebral hemorrhage

John Vance Lauderdale * Major U. S. Army retired Brooklyn Medical Department of the University of the City of New York 1862 entered the Army as an assistant surgeon in 1867 and retired in 1896 for physical disability aged 68 died January 22

Harold Alexander Patterson New York University of Buffalo School of Medicine 1917 member of the American College of Physicians on the staff of the Manhattan State Hospital Wards Island, aged 36 died, February 17 of cerebral hemorrhage

Charles Sewell Barrell Boston Harvard University Medical School, 1900 member of the Massachusetts Medical

Society aged 63 died February 16 in the Massachusetts General Hospital, of cerebral hemorrhage, arteriosclerosis and myocarditis

William Alexander Brittin, Virden, Ill. Marion-Sims College of Medicine St. Louis 1895 member of the Illinois State Medical Society aged 64 died, February 11, in St. John's Hospital, Springfield, following gangrene and amputation of his leg

Howard A Hanaford * Newport, N. H. Baltimore Medical College 1900 past president of the Sullivan County Medical Society on the staff of the Carrie F. Wright Memorial Hospital aged 55, died February 9, of meningitis following influenza

Henry Alston Killion, Portageville, Mo., University of the South Medical Department Sewanee, Tenn. 1901 Barnes Medical College, St. Louis 1904, University of Nashville Medical Department, 1904, formerly mayor, aged 49, died, in February

Ralph Robert Charlesworth, Wildwood N. J., Jefferson Medical College of Philadelphia, 1904 served during the World War on the staff of the Millville (N. J.) Hospital aged 50 died, February 12 in the Jefferson Hospital, of cirrhosis of the liver

Duncan Williamson Blake, Sr, Gloucester City, N. J. Jefferson Medical College of Philadelphia, 1876 Civil War veteran formerly coroner president of the board of health and member of the board of education, aged 82 died January 28

William S Glenn, Sr, State College, Pa., Eclectic Medical Institute, Cincinnati 1883, for many years a member of the school board aged 72 died in January, in the Jefferson Hospital, Philadelphia, of chronic nephritis and cerebral hemorrhage

Robert Eugene Barker, Kansas City Kan., Kansas City Medical College 1900 member of the Kansas Medical Society aged 56 died, February 17 in the Bethany Hospital of acute dilatation of the heart following an operation for gallstones

Charles Henry Schenk, Lagrange Ind. Curtis Physio Medical Institute Marion, 1894 member of the Indiana State Medical Association served during the World War, aged 60 died, February 5, of carcinoma of the stomach

Edwin M Hollingsworth, Mount Airy N. C. College of Physicians and Surgeons Baltimore, 1886 member of the Medical Society of the State of North Carolina aged 65, died, February 10 of a self-inflicted bullet wound

Edwin Whittier York * Newark N. J. University and Bellevue Hospital Medical College 1917 proprietor of the Newark Hospital aged 37 died February 13 of cerebral hemorrhage nephritis and hypertension

Lemuel Arthur Bassett, Boone, Iowa Rush Medical College Chicago 1896 member of the Iowa State Medical Society on the staff of the Elanor Moore Hospital, aged 63, died February 7, of angina pectoris

Inez Ford Nason, Dover N. H. Woman's Medical College of Pennsylvania Philadelphia 1890 member of the New Hampshire Medical Society aged 66, died January 15, in Bradiord Vt. of heart disease

John Valentine Fisher, Philadelphia University of Pennsylvania School of Medicine Philadelphia 1886 member of the Medical Society of the State of Pennsylvania aged 78 died February 13, of heart disease

William Granville Sykes, Aberdeen Miss. Medical Department of the University of the City of New York 1870 Confederate veteran formerly member of the state legislature aged 85 died January 18

Hugh Angus Macaulay * Waverly Mass. University of Louisville (Ky.) School of Medicine 1908 past president and secretary of the Burke County Medical Society aged 45 died February 4 of pneumonia

John Donovan Weibel Pittsburgh Vanderbilt University School of Medicine Nashville Tenn. 1909 aged 26 intern at the Mercy Hospital where he died February 17 following an operation for appendicitis

Archibald J McKillop, Wolverine Mich. Medical Department of the University of Wooster Cleveland 1887 member of the Michigan State Medical Society aged 67, died February 4 of heart disease

Robert Edward Webster Marland Ont. Canada McGill University Faculty of Medicine Montreal Que. 1891 member of the American College of Surgeons aged 60 died February 9 in San Diego, Calif.

Louise Forbes Ferro, San Bernardino, Calif (licensed by the Minnesota State Board of Medical Examiners, year unknown), aged 87, died, February 2, of myocarditis and arteriosclerosis

Pearl Mary Foster Bigelow, Utica, N Y, Syracuse University College of Medicine, 1903, aged 52, died, Dec 27, 1930 in the Utica State Hospital, of cerebral arteriosclerosis and chronic nephritis

Edwin A Mendell, St Joseph Mo, Cotner University Medical Department, Lincoln, Neb, 1892, member of the Missouri State Medical Association, aged 69, died, January 14, of carcinoma

Jefferson Cawood Newman, National Soldiers Home, Va Tennessee Medical College Knoxville 1892 on the staff of the National Soldiers Home, aged 59, died, February 8, of heart disease

Angelo Audi, Union City, N J Royal University of Turin Faculty of Medicine and Surgery, Turin, Italy, 1903, aged 52 died January 25, of carcinoma of the rectum and cerebral hemorrhage

Charles Bartels, New York Medical Department of Columbia College New York 1888 member of the Medical Society of the State of New York, died, January 7, of chronic myocarditis

William C Dewberry, Pensacola Fla, Medical College of Alabama, Mobile 1891 member of the Florida Medical Association also a druggist, aged 64, died, January 25, of pneumonia

James Clark McGuire, Washington D C, Medical Department of Columbian University Washington, D C 1879 aged 78, died, January 21, of coronary thrombosis and arteriosclerosis

Herbert Daniel Burnham * New York, Medical Department of the University of the City of New York 1889 aged 72, died, February 3, of chronic nephritis, uremia and endocarditis

Maurice Barret Pearlstien * Brooklyn Eclectic Medical College of the City of New York, 1889 on the staff of the Univ Hospital aged 54, died, January 11, of angina pectoris

W F McCurdy, Weston, Ga, Atlanta Medical College, 1884, member of the Medical Association of Georgia formerly mayor of Richland, aged 71 died February 6 of pneumonia

George Andrew King, Kansas City, Mo Rush Medical College, Chicago, 1904 aged 53, died, January 29, in the Wesley Hospital, of cirrhosis of the liver and myocarditis

Andrew Allison O'Daniel, Wildwood, N J, Jefferson Medical College of Philadelphia 1884, served during the World War aged 67, died, January 25, of cerebral hemorrhage

Edmund Scott Dow, Boston, Harvard University Medical School Boston 1887 member of the Massachusetts Medical Society aged 69, died, February 6, of lobar pneumonia

Walter Brooks Hughes, Newport Ky, Eclectic Medical Institute, Cincinnati 1914 served during the World War, county coroner, aged 38, died, February 6, of influenza

Lyman Austin Crim, Indianapolis, Indiana Medical College, Indianapolis, 1878, formerly a druggist aged 78, died, February 5 of angina pectoris and chronic myocarditis

Cora Turner Saxe * Seattle, University of Michigan Medical School, Ann Arbor, 1886, aged 71 died, January 31, of chronic myocarditis following a cholecystectomy

Louis W Palmer, Pentwater, Mich, Kentucky School of Medicine, Louisville 1877, veteran of the Spanish-American War, aged 73, died February 8, of heart disease

George L Fox, Linden, Md Medical Department of Columbian University Washington, D C, 1885 aged 74, died, January 14 of pyelonephritis, uremia and cystitis

James Curtis Watts * Rome, Ga, Eclectic Medical Institute, Cincinnati, 1881, on the staff of the McGill Hospital, aged 70 died February 3 of coronary thrombosis

Thomas Alphonsus Wallace, New York Medical Department of the University of the City of New York 1893, aged 65 died Nov 10 1930 of chronic myocarditis

Joseph Moses Ward Kitchen, East Orange N J Medical Department of Columbia College New York 1881 aged 84 died February 3, of hypostatic pneumonia

John Stennis Adams, Sumrall, Miss, University of Nashville Medical Department 1901 aged 52, died in February, in a hospital at Hattiesburg, of pneumonia

Anna Belle Davis Parker, Gilmanton N H, Boston University School of Medicine, 1898, aged 61, died, February 10 in Worcester, Mass, of heart disease

George Sherman Blake, Rockville, Ind, Bellevue Hospital Medical College, 1892, aged 66, died, January 30, in Tempe, Ariz, of ruptured gallbladder

George C Holland, Dallas, N C, Baltimore University School of Medicine, 1890, formerly mayor of Bluefield, W Va, aged 66, died February 4, of uremia

William C McNeal, Hoehne, Colo, Jefferson School of Medicine, Louisville, 1882, aged 76, died, January 12, in a hospital at Trinidad, of pneumonia

Thomas Baird Allison, Tarentum, Pa, Western Pennsylvania Medical College, Pittsburgh, 1896, aged 69, died, Dec 11, 1930, of acute myocarditis

John H Young, Burkeville Va, Southern Medical College, Atlanta 1882, member of the Medical Society of Virginia, aged 71, died, Dec 22 1930

Carl Orth, St Louis St Louis College of Physicians and Surgeons, 1891, aged 67, died, February 15, in the Deaconess Hospital, of pneumonia

Samuel Joseph Chesnut, Bambridge, Ga, University of Maryland School of Medicine, Baltimore, 1892, aged 68, died, February 10, of uremia

B F Hancock, Nashville Ark, Medical Department, University of Tennessee, 1881, aged 76, was found dead, January 20 of heart disease

Marcus M Rhoades, Graham, Mo, St Louis Medical College, 1868, Civil War veteran, aged 90, died, January 16 of arteriosclerosis

George Lewis Guthrie, Madison, Ind, Medical College of Indiana, Indianapolis, 1900, aged 53, died, February 12, of heart disease

Charles Lorain Harrod, Indianapolis, Medical Department University of Tennessee, 1893, aged 67, died, January 23, of heart disease

John James Irven, Montreal, Que, Canada, McGill University Faculty of Medicine, Montreal, 1911, aged 43, died, Dec 6, 1930

C B Baird, Sharon, Tenn, Vanderbilt University School of Medicine, Nashville, 1886, aged 66, died, January 24, of pneumonia

William J Bryan, Valhalla, N Y, Eclectic Medical College of the City of New York, 1879, aged 72, died, February 9, of senility

Sophia C Davis, Augusta, Ga Georgia College of Eclectic Medicine and Surgery, Atlanta, 1894, aged 80, died, January 16, of senility

Nicholas I Scott, Norwood Ohio Medical College of Ohio, Cincinnati, 1881, aged 79, died, February 12, of diabetes mellitus

Oliver P Branson, Wichita Kan American Medical College, St Louis, 1895, aged 76, died, February 5, of heart disease

William A Ewing, Washington, Okla, University of Louisville (Ky) School of Medicine, 1893, aged 68, died, Dec 12, 1930

John James Carroll * Naugatuck, Conn, Dartmouth Medical School, Hanover, N H, 1897, aged 72, died Dec 17, 1930

Robert X Wade, Coyle Okla (licensed, Oklahoma, under the Act of 1908), aged 75, died, Dec 29, 1930, of lobar pneumonia

Edward John Free, Campbellford, Ont, Canada, Victoria University Medical Department, 1887, aged 71, died, Nov 16, 1930

Daniel B Taylor, Gary, Ind Meharry Medical College, Nashville, Tenn, 1903, aged 51, died, January 27, of pneumonia

Ammi Sibley Nichols, Portland, Ore Hahnemann Medical College of Philadelphia, 1876, aged 77, died, January 23

William N Tate, Mebane, N C, Louisville (Ky) Medical College 1875 aged 85, died January 26, of arthritis

Thomas A Cook, Democrat, Ky, Louisville Medical College 1893 aged 65, died January 30 of appendicitis

Jay C Norris, Birmingham, Iowa (licensed, Iowa, 1887), aged 75, died, February 7

Bureau of Investigation

SCAR-POX

An Alleged Cure for Smallpox and Scarlet Fever

State and local health officials from Michigan to California have received a form-letter coming from the White Laboratories of Chicago, offering to send on request a free trial treatment of "Scar-Pox." Among the claims made for Scar-Pox in the letter just referred to are these:

Scar-Pox, the new and guaranteed remedy for scarlet fever or smallpox.

Scar-Pox is the tested remedy for the cure of either dread disease scarlet fever or smallpox.

It is a vegetable compound absolutely pure.

It is guaranteed by the makers to absolutely cure either scarlet fever or smallpox in three days when used as directed.

The White Laboratories, according to the letterhead are "Manufacturing Chemists" and are the Sole Makers of Scar-Pox. The letters sent out by the White Laboratories are signed "J. White." The address given is 309 South LaSalle Street Chicago. The Chicago telephone directory does not contain the name of these manufacturing chemists—the White Laboratories. A visit to 309 South LaSalle Street also disclosed the fact that the White Laboratories are not listed in the office directory of that building. Neither did the men who operated the elevators of the building know where the White Laboratories could be found. A visit was made however to a large, and not too prepossessing office in this building housing according to the names on the door, the "All Trades Employment Bureau" and the "Chicago Garage Owners Exchange." Inquiry for the persons who represented the "White Laboratories" brought out from one of the partitioned departments, Mr. White.

The representative of the Bureau of Investigation told Mr. White that a number of inquiries were being received regarding his product, Scar-Pox, and Mr. White was asked whether he was willing to give any information regarding his product so that such questions might in the future, be answered more satisfactorily. Mr. White was not willing. He did make some vague statements to the effect that Scar-Pox was a preparation that had been originated by a German. When asked whether the product had ever been tested in the United States, Mr. White said that it had, on three cases in California and one case in Chicago—in both instances, apparently, under his rather than medical auspices. On the matter of composition, Mr. White was as noninformative as the average patent medicine label. When asked where the White Laboratories were located, Mr. White stated that they were at his home.

The circular letter already referred to offered to send to any health department or board of health one regular pint size of Scar-Pox for a test. Accompanying the circular letter was a return postcard. Those health officials who filled out the return card received in due time a pint bottle of Scar-Pox. The label on the bottle carried, in addition to directions, the following "Notice":

Scar-Pox is an internal medicine and is to be used internally only. It is not a toxin or a preventative and should be used only when either disease scarlet fever or smallpox is actually contracted. It contains no narcotics of any kind alcohol or injurious drugs. SHAKE WELL BEFORE USING.

The patient with smallpox was directed by the label to drink half a glassful twice daily till relieved. According to the same label one bottle of Scar-Pox was sufficient for most cases. The directions further stated that in the smallpox sufferer was unconscious or helpless forced drinking is advisable. The only other information of interest on the label was the statement that this bottle of Scar-Pox was sold at \$15.

In addition to the bottle of Scar-Pox that the health officials received, there came a follow up letter to the effect that should the official desire to reorder shipments would be made the same day as the order was received and that the prices would be \$15 a pint or \$150 for a case of twelve pints. A postcard would be sent by air mail for \$2.75 additional to any part of the United States.

Some unopened, original bottles of Scar-Pox were submitted by the Bureau of Investigation to the A. M. A. Chemical Laboratory for analysis. The chemists' report follows:

LABORATORY REPORT

"Some original bottles of 'Scar-Pox' (White Laboratories Manufacturing Chemists, 309 South LaSalle Street Chicago U. S. A.) were submitted to the A. M. A. Chemical Laboratory by the Bureau of Investigation for examination. The bottles contained an average of 450 cc. (approximately 15 fluid ounces) each of a colorless liquid with some suspended material having a slightly stale odor and an acidulous taste. The reaction of the mixture to litmus was decidedly acid. No statement as to the composition was given on the label.

Qualitative tests indicated the presence of potassium, tartrate traces of chloride and sulphate, water, a substance precipitable by alcohol suggestive of potassium acid tartrate (more commonly known as cream of tartar). Heavy metals and alkalis were not found.

The specific gravity at 20 C was 1.002. The total solids were found to be 0.67 per cent, consisting essentially of small colorless rhombic crystals (responding to tests for potassium acid tartrate). This amount of potassium acid tartrate was also indicated by titration. The amount of water by difference was found to be 99.33 per cent.

From the foregoing tests it is concluded that Scar-Pox is essentially a saturated aqueous solution of commercial cream of tartar (about 0.6 Gm. in 100 cc.).

Summed up then, it is evident that this "new and guaranteed remedy for scarlet fever or smallpox" that is guaranteed by the makers to absolutely cure either scarlet fever or smallpox in three days is nothing more than cream of tartar in water. Less than one half cent's worth of cream of tartar in a short pint of water selling for \$15! One of the most astounding features of modern civilization is the fact, verified daily that any person however ignorant of medicine or pharmacy, can put up the most fantastically worthless mixtures and sell them as 'cures' for some of the most serious diseases known and there is no legal machinery for stopping it—unless the exploiter is so crude as to violate either the national Food and Drugs Act or the postal laws against fraud! In the present instance J. White is sufficiently ignorant so that he apparently would violate both the postal laws and the national Food and Drugs Act. This does not however change the fact that with a little more fitness he could pursue this barbaric trade with impunity!

QUACKERY IN PENNSYLVANIA

Showing What One Newspaper Did to Protect the Public Against Charlatans

Last July the Philadelphia Record started to look into the problem of medical quackery and published a most meritorious and enlightening series under the general title "Bootlegging the Healing Arts." The Record called for no help from the medical profession, either locally or nationally. The Bureau of Investigation although it has a vast amount of data some of which of course is on Philadelphia quacks was not asked to furnish a line of information. Nevertheless because the Philadelphia Record went after quacks aggressively that paper was immediately accused of being but the cat's paw of the American Medical Association—the Medical Trust!

What the Philadelphia Record accomplished with the help of the local law-enforcing bodies is succinctly told in an editorial published by that paper January 19 last under the title "Quackery Can Be Suppressed." The editorial follows:

Thirty-seven cases, thirty-five convictions, one permanent and one discharge on benefit of the doubt—the unprecedented record made in the quackery prosecutions.

"Three jury verdicts of guilty, three convictions on the bench. These are the results of evidence gathered by the local and preserved with masterly effect by the District Attorney here under the impartial leadership of Judge Ferguson.

"No undertaking undertaken in such a manner as to be carried through in more impressive accordance. It resulted

compliments from three sources—in congratulations from the prosecutor and the Court, and in a defense attorney's plea to a jury

"The *Record* didn't do this to correct an abuse but to sell papers to gain circulation. Its idea was that the more doctors it could send to jail the more dividends it could pay

"Those slurs afterward withdrawn, justify a frank statement. "First, the *Record* was not so unsophisticated as to expect that a crusade of this nature would add to its circulation, and in fact the project resulted in no gain of that nature

On the contrary the *Record* foresaw that exposure of the quacks would offend many practitioners and a multitude of their followers. And, in fact, the publicity made more enemies than friends for the publication

The truth is exactly as stated by Mr. Hermes. "The *Record* discovered systematic violation of State laws and employed investigators at its own expense to get evidence that would end the abuses"

"Incidentally, complaints of 'persecution' by 'the medical trust' are as baseless as the others. The medical profession studiously remained aloof doubtless from fear of being accused of a desire to suppress competition

"All these, however, are now minor considerations. It is of real importance that the blow given to quackery should lead to better protection of the public health in the future

"Eventually measures should be taken to revise the whole system of licensing practitioners of the various methods of treating disease. But meanwhile there is urgent need for real enforcement of existing law

"That it is now virtually suspended, that a newspaper had to drag flagrant violators to Court, is due to lack of funds by the State Medical Board

"It is the duty of the medical profession to insist that the Legislature make adequate appropriations for this purpose, and that the responsible agency rid the State as it can of unlicensed frauds and incompetents masquerading as doctors

Correspondence

COLLECTION AND FINANCE COMPANIES

To the Editor—In view of the number of letters printed in THE JOURNAL, February 14, making complaints against certain collection and finance companies, it would appear that the problem is perennial

Several years ago, members of the Academy of Medicine of Cleveland were pestered with solicitations from a large number of collection agencies. After taking counsel, we wrote our members asking them to list with us the names and addresses of the companies with whom they had placed accounts in the few years preceding. We also asked for some comment as to the efficiency of the companies mentioned. The result was astonishing. The number of companies or individuals was four or five times larger than either the Academy or the Better Business Bureau of Cleveland realized

We then wrote to all these companies informing them that we were continually receiving requests for information from our members about them and their services and asking that they file with us copies of their contracts and a statement of their methods of operation together with names of some physicians with whom they had had satisfactory dealings. We explained that with facts on hand we could intelligently answer queries, without facts we would have to inform our members that there was no local information available about the company

As a result companies who had a local reputation of merit promptly furnished us with the material requested. Those who apparently had something to conceal refused to comply with our request. We then wrote to all our members, instructing them to call us every time a new solicitor appeared, concerning whom they had no information or personal knowledge

The result succeeded beyond our expectations. So far as we know, Cleveland has since been relatively free from the fly-by-night agencies. While many have attempted to open here they have not remained long nor have they obtained many accounts

We have repeatedly pointed out to our members certain methods of avoiding collection difficulties as follows

- 1 Accurate bookkeeping and regular billing by the physician.
- 2 Where collection is necessary
 - (a) Employment of an individual personally known to the physician
 - (b) Employment of a local collection agency whose reputation has been established by service covering several years
 - (c) Affiliation with retail credit companies or similar organizations operated by local merchants and professional men
 - (d) Prompt communication with our executive office whenever a solicitor of an unknown company makes a bid for accounts

This campaign (which is really not a campaign, but a continuous service) has been made possible and effective by cooperation with the executive office of the American Medical Association, in checking the national standing of unknown firms and by the cordial help and support of the local Better Business Bureau, which has made many investigations for us

H. VAN Y. CALDWELL, Cleveland

Executive Secretary, Academy
of Medicine of Cleveland

BLOOD CHEMISTRY VALUES

To the Editor—I am submitting a table of blood chemistry values which I have found practical and easy to remember

Total nonprotein nitrogen	30-40
Urea nitrogen	10-20
Uric acid	3-4
Creatinine	1-2

All values in milligrams per hundred cubic centimeters of blood

If the figures are read from the bottom up they are 1, 2, 3, 4, 10, 20, 30, 40. One needs only to bear in mind that the upper figures are high normals and even the slightest increase above the upper figure indicates pathologic change

This was first suggested to me by some one in my graduating class (University of Colorado, 1927)

This may be of value to those who cannot recall blood chemistry normals at random. JULIAN LOVE, Brooklyn

Lieutenant (j g) M. C., U. S. Navy

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request

PATHOLOGY IN DEATHS FROM ETHYL ALCOHOL METHYL ALCOHOL AND CANTHARIDES

To the Editor—What does postmortem examination reveal in cases of death due to ethyl alcohol, methyl alcohol or cantharides? What is the fatal amount of ethyl alcohol in a normal individual if there is a fatal dose? Would you please recommend a textbook on pharmacology and toxicology that is concise?

JAMES B. BURCHAM, M.D. Gary, Ind.

ANSWER—After death from acute poisoning with either ethyl or methyl alcohol, the usual changes are congestion of the lining of the stomach and duodenum with many small hemorrhagic extravasations, congestion and edema of the brain and its membranes and also of the lungs. In neither case are there any distinctively characteristic changes. After death from acute alcoholism the odor of alcohol may be detected from the contents of the stomach and the brain

After fatal poisoning by cantharides there will be found acute gastritis and enteritis as well as nephritis with perhaps acute inflammation in the lower part of the urinary tract. There may be blisters in the mouth and stomach, if the powdered cantharides has been taken there may be present in the stomach characteristic green, shining particles

The fatal dose of ethyl alcohol will vary depending on individual susceptibility, concentration of the alcohol taken, the

previous contents of the stomach and so on. Consequently no single quantity has been established as the average fatal dose. In most of the fatal cases, from 1 to 2 pints of whisky or brandy was reported as taken, which would correspond to from about 250 to 475 cc. of pure alcohol. In many cases a smaller quantity no doubt would be fatal. From 100 to 200 cc of pure grain alcohol may be regarded as the minimal fatal dose if taken at one time in concentrated form. Infants have died from two tablespoonfuls of brandy, and from 30 to, say 120 cc of absolute alcohol may be regarded as probably fatal to most children under 12 years of age, but Herter (*New York M J* 64 608, 1896) has reported an instance in which a child of 3½ years recovered after taking 12 ounces of whisky, that is, approximately 355 cc of alcohol.

Cushman's Text-Book of Pharmacology and Therapeutics revised by Edmunds and Gunn, now in its ninth edition and Sollmann's Manual of Pharmacology and Its Application to Therapeutics and Toxicology, third edition, are standard textbooks in their fields.

EXAMINATION OF VAGINAL SMEARS FOR TRICHOMONAS

To the Editor—Will you kindly give the method of examination of fresh smears for *Trichomonas vaginalis*? Please omit name.

M D Michigan

ANSWER—The word smear generally refers to a preparation that is stained and then examined for organisms. This is not the method for studying *Trichomonas vaginalis* especially for one who is not thoroughly familiar with these parasites. The way to detect *Trichomonas vaginalis* is by the simplest form of microscopic examination; namely, an examination of a drop of the fresh secretion obtained from the vagina. The drop of secretion may be obtained with a platinum loop from the vault of the vagina after exposure with a speculum. A more simple method is to make a vaginal examination on withdrawal, a moderate amount of secretion will be found adherent to the gloved fingers. For making slides the discharge that is high up in the vault and close to the vaginal wall should be used and not the discharge that is on the surface. One or more drops may easily be placed on cover slips or slides. If this method is used and the glove is dry when drawn on, the dusting powder should be washed off with soap and water before the vaginal examination is made. No antiseptic or lubricant should be used on the glove. For studying the organism fields should be selected where there is relatively little discharge, namely at the periphery of the drop of secretion. The drop usually consists of a large number of leukocytes and bacteria, many epithelial cells and many trichomonads. For the beginner it is best to add a drop of salt solution to the drop of secretion and then make the examination. With the ordinary high power lenses the parasites may be readily seen because of their motility. The trichomonads vary considerably in size. Usually however they are larger than a polymorphonuclear leukocyte but smaller than an epithelial cell. The organism varies in shape but usually it is spindle shaped or pyriform.

HAZARDS TO WORKERS IN STORAGE BATTERY INDUSTRY

To the Editor—F. C., a man aged 20 working in a factory in the manufacture of storage batteries has no direct contact with lead. His job is in the acid room where the lead plates are immersed in sulphuric acid connected in series and charged with an electric current for forty eight hours. He complains that his teeth are becoming yellow and that he cannot keep them white. The central incisors in spite of dental care show decay of the enamel. In addition there have been vague gastro-intestinal symptoms for a month especially attacks of dull epigastric pain, globus and local distention which wake him out of his sleep several times a night and for which he seeks relief. Is there such a thing as sulphuric acid poisoning? The room although large is permeated with its fumes. Kindly omit name.

M D Connecticut

ANSWER—There is no inherent lead hazard in the acid room of a storage battery factory. Cases have been observed in such work but invariably these may be traced to unusual circumstances, such as currents of air bearing lead dusts sweeping in from other rooms.

Sulphuric acid as used in this industry does not evaporate. As the result of mechanical action or thousands of minute bubbles created in the battery as a result of chemical action some sulphuric acid is thrown out into the air and may be inhaled. Workers exposed to this nebulized sulphuric acid frequently complain of damaged teeth and gastro-intestinal disorders. There is no reason to believe that sulphuric acid as such, long exerts after contact with the body, nevertheless the

number of cases detectable under exposure of this sort justifies the recognition of some deleterious influences. McCord and Friedlander (*Am J Pub Health* 16 274 [March] 1926) have reported a series of gastro-intestinal ulcerations or severe inflammations among galvanizers. In this industry the nebulized sulphuric acid combined with vapors of zinc oxide from the galvanizing kettle forms zinc sulphate. This acid-like substance was accepted as responsible for the gastro-intestinal disturbances encountered.

It in the present instance lead exposure may be ruled out and if acid actually is present it is reasonable to consider as probable some influence direct or indirect, from the acid on the mouth and gastro-intestinal tissues.

OPERATION OF CHOICE FOR SEXUAL STERILIZATION IN THE FEMALE

To the Editor—What at this time is considered the best operation for sexual sterilization in the female as shown by reported failure? Is the Madlener operation considered entirely satisfactory? We have been doing double crushing and ligating of the tube and have had no reported failure. In other institutions of this state they have preferred resection at the cornu of the uterus.

H C HENDEL M D Peterburg Va

ANSWER—Madlener (*Zentralbl f Gynäk* 50 219 1926) reported 128 cases in which he crushed and ligated the tubes according to his technic. The results were 100 per cent perfect, no pregnancy followed. Simple crushing and ligation of the tubes (Madlener angulates crushes and ligates) cannot be depended on. Pregnancy follows occasionally despite most pains taking technic. The most satisfactory and most widely accepted technic consists in excision of a portion of the tube at the uterine cornu with careful burying of the tubal stump in the broad ligament and painstaking suturing and peritonization of the uterine wound. It is well to bear in mind that removal of the fundus of the uterus not only sterilizes with certainty but may also rid the patient of the danger of subsequent bleeding or discomfort from a heavy dragging uterus.

HAZARDS OF SAND BLASTING

To the Editor—A corporation that I serve has asked me to inform it regarding the accuracy of a statement made by Dr. W. A. Evans in his syndicated article published recently entitled Steel Grit Blasting. It states:

The sand blasting industry is discovering that fine steel grit powder in many respects is superior to silica sand. Sand can be used only once in blasting because the force breaks up the particles and smooths off the corners and makes the sand useless. Steel grit dust can be used over and over again.

Sand is light and air currents carry it over everything. Steel grit is heavy falls out of the air and does not soil the neighborhood. When sand is used for blasting the cloud of dust makes it difficult for the workers to see around them. Not so with the steel grit dust. And overshadowing the other advantage of steel grit is its greater safety for employees. The man who works at sand blasting is so easily prone to develop silicosis a form of lung disease which is quite similar to consumption probably due to infection of tissues put in condition for infection by the dust.

In New York State a married man the father of four children recently died from silicosis. He was a sand blaster and the disease was a result of his occupation. His case went up through various boards and finally through the court and came to rest with the following, sententious formula: Cause of death silicosis. No compensation. Society may have to care for the family. When the man worked at his trade he always wore a hood and stayed in his dust cabinet. This cabinet and also the hood was attached to exhaust ducts through which fans drew away the dust laden air. It is believed that hoods of this type are sold or worn in sand blasting. The point is so fine that it will go into the hood in front of all that can be seen. The approved sand blaster's hood has air pumped in out of the atmosphere. The pressure is maintained inside of it. This is more effective in keeping out dust.

Have you any information which would as to the accuracy of the foregoing statement? L. A. T. H. L. D. O. V.

ANSWER—The United States Public Health Service in cooperation with the National Safety Council has been conducting over a period of many months an investigation of the hazards of sand blasting. No general report has been made although some information has been supplied to cooperating agencies. Until a full report is available it is doubtful that no fixed opinion or sand blaster and the relative merits of steel grit and sand can be expressed.

At this time it is proper to mention the following:

1. The use of silica sand for blasting is dangerous. 2. The use of steel grit for blasting is safer. 3. The use of steel grit for blasting is safer than the use of silica sand. 4. The use of steel grit for blasting is safer than the use of silica sand. 5. The use of steel grit for blasting is safer than the use of silica sand.

siliceous rock) buildings the cut surface rather than the cutting agent provides a highly dangerous silica dust.

2 The lifetime of steel grit used in blasting is not so extended as implied in the quotation in the query. The sharp cutting edges of steel particles are dulled by use and require replacement. Special steels possess properties permitting longer use but increased costs limit application.

3 Dust dispersion is greater for sand than for steel particles. This property is favorable to the use of steel grit.

4 Silicosis is prone to develop in any sand blaster long engaged in this work and unprotected by work conditions and appliances that obviate dust. Silicosis is however not an infectious disease. Tuberculosis may be superimposed on a silicosis but the latter state is an entity of chemical or mechanical (or both) origin.

5 Silico is acceptable for industrial compensation only in California, North Dakota, Wisconsin, Massachusetts and Connecticut. This state must be subject to recent changes. No effort has been made to check the specific case mentioned in the query but cases of this character are known to exist. A grave social injustice is being done in the discrimination against silicosis as an occupational disease in connection with compensation.

6 The usual type of mask or hood employed in the average dust trade is of restricted value in sand blasting. Positive pressure breathing helmets are preferable.

A recent discussion of this occupation may be found in an article entitled 'Ueber die Verwendung von Stahlschlacke in Sandstrahlgeblasen' by G. H. Zirkler, Gusserei (Düsseldorf), December 1930, volume 17, number 50, pages 1189-1197. This article gives a comparison of natural products—quartz, sand, river sand—with technical products, such as steel sand. Photostatic copies of this foreign article may be obtained at a low cost by writing to the Engineering Society Library, 29 West Thirty-Ninth Street, New York.

METALLIC TASTE IN MOUTH

To the Editor—A woman aged 21 has complained of a metallic taste in her mouth with a slight tendency toward salivation for the past two years. She has always been healthy, especially during the past three or four years during that period she has not received medication of any sort. She has never smoked, does not drink, eats a well-balanced diet and leads a routine life. The metallic taste persists constantly, the only relief being the partial obscuring of the taste while eating. The taste is most noticeable along the gum margin. Examination shows a healthy girl and repeated examinations show absolutely no pathologic conditions. The mouth is clean, the gums are healthy. There are a few gold fillings which have all been in more than three years. A thorough analysis of the source of foods does not show any way in which the patient could be getting metal. The cosmetics and tooth paste are all from reliable firms. She had been using zinc stearate between her toes but she has discontinued this without relief of symptoms. She is employed as a bookkeeper in a business office. No one in her home is employed where there would be contact with any metal. The patient is not the type prone to hysteria. She has been to other physicians who have done nothing for her. I find nothing in the literature about such a condition and would appreciate any suggestions. Please omit name. MD New York.

ANSWER—The cause of the metallic taste with otherwise completely negative observations would certainly suggest a psychoneurosis. Hallucinations of smell and taste occasionally occur in temporal lobe tumors, in which case other symptoms will soon appear. It is worth while attempting psychotherapy for this isolated subjective symptom.

USE OF INSULIN TO INCREASE WEIGHT

To the Editor—I have a patient who is suffering from malnutrition and the accompanying underweight. All attempts to overcome this have up to the present been unsuccessful. I have heard reports that insulin has been used with success in these cases but what literature I have read on the subject does not confirm this. Can you give me any information or references?

J MILTON HENRY MD Chicago

ANSWER—There have been many favorable reports concerning the use of insulin for increasing weight. A concise review of the work reported in this country may be found in the paper by James J. Short, MD, 'Increasing Weight with Insulin' (*J Lab & Clin Med* 14:330 [Jan.] 1929). This author ascribes this effect of insulin chiefly to the strong sensation of hunger which it produces and advocates doses of about 10 units three times a day before meals. He favors a rather high fat diet with insulin since the hunger occasioned by insulin may in some cases be allayed by relatively small quantities of carbohydrates.

An excellent review of the German literature on this subject may be found in the small monograph by Frank and Wagner, 'Insulintherapie' (Leipzig: Georg Thieme, 1931). These authors discuss the theoretical considerations involved in this action of insulin such as the retention of water and its influence on fat, protein and carbohydrate metabolism. They advocate doses of

at least 40 units a day and as much as 20 units three times a day. With such doses, of course the carbohydrate intake must be sufficiently great to avoid severe hypoglycemic reactions. The patient should receive, half an hour after the injection, at least 15 or 2 Gm of carbohydrates for every unit of insulin injected. Even so the patient may have symptoms of hypoglycemia within two or three hours. He should therefore have in readiness a snack of some sort with which to satisfy his hunger and relieve his symptoms. A chocolate bar is suggested as a convenient emergency ration.

DEMENTIA PARALYTICA

To the Editor—Can an individual in whom serologic examination of both blood and spinal fluid is negative have dementia paralytica in any of its stages? Could he be in evolutionary stages and show negative serologic results? In *Harvey's Handbook on Venereal Disease* 1930 edition, page 59 I note what he terms 'pseudogeneral paralysis' and he indicates that the patient does not lose the power of self-criticism and the realization of time and space are not lost unlike the general paralytic. The patient realizes he has something wrong with his brain and fears that he may be going mad. This disease he says is caused by diffuse cerebral endarteritis and often is combined with cerebral gummas. Would a patient with pseudogeneral paralysis necessarily have to show a positive serologic picture? How long would he be supposed to live? Would he be protected from the effects of overt acts in a medicolegal way the same as in general paralysis? Please omit name. MD Tennessee.

ANSWER—There is some question as to whether a diagnosis of dementia paralytica can be made in the presence of both negative blood and spinal fluids. It is possible that an occasional patient with the mental symptoms of this disease may have a negative Wassermann reaction. Neurologists are usually the men who demand a strongly positive Wassermann reaction in both spinal fluid and blood in a nontreated case before they will make the diagnosis.

In the meningeal types of syphilis, of which the diffuse cerebral endarteritis is a part, there may be a completely negative blood and spinal fluid in the presence of mental symptoms. If the patient has mental symptoms, they should be controlled but would follow the medicolegal aspect of any insane patient. One cannot say how long life can be prolonged. With treatment it will probably be much longer, but without treatment disease will probably last longer than in a case of dementia paralytica without treatment.

POSSIBILITY OF PREGNANCY AT MENOPAUSE

To the Editor—I have a patient who has not menstruated since late March. She is 45 years of age and has two children, the youngest of whom is 12 years of age. She has the various symptoms of the menopause. She is anxious to know whether there is even a remote possibility of again becoming pregnant. Can I tell her positively that it is impossible for her to become pregnant? Please use my initials only and no address. MD New York.

ANSWER—This patient should not be told positively that it is impossible for her to become pregnant. In spite of the fact that she has not menstruated for ten months and has symptoms of the menopause, there is a possibility that she may again conceive because impregnation may occur during or after the menopause. As a rule when conception takes place after the menopause it does so within a year of the last menstrual period, but women have also become pregnant a number of years after the cessation of the menses. In some of these cases impregnation takes place following a long period of amenorrhea, whereas in other instances the menstrual flow returns a number of years after the menopause and it is at this time that conception may occur.

HOARSENESS DURING MENSTRUAL PERIODS

To the Editor—A girl aged 15 years for the past two years has been getting hoarse a few days before her menstrual period and the hoarseness continues into the period. She has a congenital amblyopia with a high error of refraction causing intense headaches; this has been corrected. Menstruation started at the age of 12 and has always been irregular and painful. I have seen her the past two months and six days before menstruation she got hoarse so she could not talk above a whisper. The condition cleared up during menstruation. There is a slight congestion of the larynx and at no time any bleeding. All other physical examinations are negative. Is this a case of vicarious menstruation? What is the treatment and prognosis? Please omit name and address. MD Texas.

ANSWER—This is not a case of vicarious menstruation because there is no actual bleeding from the mucous membrane of the throat. Vicarious menstruation refers only to those rare instances in which hemorrhages occur in extragenital organs at regular intervals which correspond with the menstrual periods.

When the extragenital bleeding entirely replaces the usual uterine flow it is called substitutional, and when it occurs along with the normal uterine hemorrhage it is called supplementary menstrual hemorrhage.

It is difficult to give a satisfactory explanation for the hoarseness in this case. There may be a psychic factor to account for it because the menstrual periods are always painful. Another possible explanation may be periodic swelling of the thyroid gland. In some women the thyroid gland regularly enlarges just before or during the menses, and this enlargement may be seen and felt. It is conceivable that such a swelling may involve the recurrent laryngeal nerves that supply the vocal cords. It is also possible that the enlarged thyroid may compress the trachea and thereby produce the hoarseness. If enlargement of the thyroid gland is the cause of the hoarseness it may be difficult to control these periodic swellings unless the administration of iodine or iodine alternating with thyroid for a few days before the hoarseness appears will help. If there seems to be a psychic factor for the hoarseness, an attempt should of course be made to overcome this.

TREATMENT OF PROGRESSIVE MUSCULAR DYSTROPHY

To the Editor—I have a patient with progressive muscular dystrophy of the scapulohumeral type. He is now about 16 years old and showed degeneration of these muscles when about 14. The physicians of a dispensary have suggested intra muscular injections of drops of epinephrine hydrochloride and 1/20 grain of pilocarpine hydrochloride. I am unable to find out why they would think that pilocarpine could possibly do this patient any good. Could you? Is this an accepted treatment for progressive muscular dystrophy? Can you give me any information about this treatment? Can you suggest a treatment that might reasonably be of service? Please omit name.

M. D. Winneva

ANSWER—As far as can be determined no treatment of any kind is of any avail for progressive muscular dystrophy. All sorts of procedures have been tried, all sorts of drug, used and of late many glandular extracts have been tried without any results. That possibly the progressive muscular dystrophy is due primarily to some metabolic disorder conditioned by endocrine dysfunction is the current feeling.

DANGERS OF CARBON TETRACHLORIDE IN SHAMPOO

To the Editor—A patient of mine is using a scalp lotion composed of fruit juices combined with carbon tetrachloride. Is such a lotion harmless? Kindly omit name.

M. D., Massachusetts.

ANSWER—Shampooing with carbon tetrachloride may cause dyspnea, vertigo and headache as the consequence of inhalation of large amounts. One death has been reported from this cause. Impure carbon tetrachloride causes a severe dermatitis. When it is used as a scalp lotion this danger would be slight, but if there is any danger whatever the use of other harmless drugs would be advisable. See Alderson H. C. Carbon Tetrachloride in Dermatology (*Arch. Dermat. & Syph.* 8:411 [Sept.] 1923).

EFFECTS OF OOPHOECTOMY

To the Editor—Is there any known drug or treatment that will ameliorate the symptoms of artificial menopause caused by bilateral oophorectomy in a young woman. My patient, a school teacher aged 21, necessarily had bilateral oophorectomy done because of large dermoid cysts of each ovary.

M. J. REYER, M.D., Goodland, Kan.

ANSWER—There is no specific treatment. Thyroid extract in small doses is the only drug of accepted value. Sodium bromide, avoidance of coffee, and life outdoors are helpful.

RENDU-OSLER WEBER'S DISEASE

To the Editor—In THE JOURNAL, Aug. 10, 1929, page 478, while I was in Europe I read the letter and your reply to the query made by Dr. H. A. Brown, Whitinville, Mass., concerning a woman about to come to labor (August 15), a "partial bleeder." She had almost unconceivable hemorrhage in her first confinement nine years previously. Her father had "pronounced hemophilia." She did not bleed abnormally after the extraction of teeth or after cuts. The doctor could not understand why the condition was not expressed in his case of "hemophilia." These cases may have been not hemophilia but instances of Rendu-Osler-Weber's disease or perhaps instances of Frank-Clauser's hemophilia. Hemorrhagic thrombasthenia, probably the former. En taxis, platelet count, bleeding and clotting time and lot retraction are not mentioned. You do not mention Osler's disease as one of the causes of hemophilia. From the lungs, bronchi and trachea in your reply to Dr. H. F. G. Loomis, Londport, N. Y. in THE JOURNAL, Aug. 1929, page 472.

Florida November Examination

Dr. William M. Rowlett, secretary of the Board of Medical Examiners of Florida, reports the written examination held at Jacksonville Nov. 10-11, 1930. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Forty-four candidates were examined, 39 of whom passed and 5 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Yale University School of Medicine	(1925)	88.9	
Atlanta College of Physicians and Surgeons	(1920)	80.2	
Emory University School of Medicine	(1916)	80.8	
(1928) 84.2 86 (1929) 84.7

Colorado October Examination

Dr. William W. Williams, secretary of the Board of Medical Examiners of Colorado, reports the written examination held at Denver Oct. 7, 1930. The examination covered 10 subjects and included 80 questions. An average of 75 per cent was required to pass. Five candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Kan. City College of Medicine and Surgery	(1911)	70	
University of Kharkov Faculty of Medicine	(1911)	70	
Osceola	(1911)	70	

Dr. Williams also reports 12 physicians licensed by the endorsement of credentials at the same meeting. The following colleges were represented:

College	Year Grad.	Per Cent
Hahnemann Medical College, Chicago	(1911)	70
Louisiana University School of Medicine	(1911)	70
P. H. Medical College	(1911)	70

McKays Medical College	(1911)	70
University of Texas School of Medicine	(1911)	70

* Verification of graduation in process.

Book Notices

THE TREATMENT OF CHILDREN'S DISEASES WITH SPECIAL FORMULAS AND DRUGS FOR CHILDHOOD AND A SHORT DIAGNOSTIC SUMMARY OF EACH CLINICAL PICTURE. By Prof. Dr. F. Lust, Director of the Children's Hospital, Karlsruhe. Authorized translation of the sixth German edition with additions by Sandor A. Levinsohn, M.D., Associate Pediatrician to the Barnert Hospital, Paterson, N. J. Cloth. Price \$8. Pp. 513. Philadelphia: J. B. Lippincott Company, 1930.

This book had already been translated into Italian, Spanish and Russian. The sixth edition now has been translated into English. There are relatively few books in English that deal mainly with the treatment of children's diseases. The translation differs in certain respects from the original in order to conform with accepted American ideas, as on diabetes and vaccination and on the dosage of tetanus and diphtheria antitoxin. Dr. Lust has furnished additional notes since the sixth German edition expressing his latest views on such things, for example, acid milk mixtures, milk free feeding, rickets, pernicious anemia, asthma, bronchopneumonia, celiac disease, spasmophilia, scarlatina and congenital syphilis. The translator has also included ideas, methods and formulas derived from other European clinics and from American authors.

This is essentially a practical book for the pediatrician and especially a guide for the general practitioner doing some pediatrics. There is practically nothing on etiology. The diagnosis and differential diagnosis are mostly in outline or compound form which seeks to recapitulate the salient features of each clinical picture in the form of a short sketch. Only the high points are touched. However, more attention is given to the diagnosis of strictly pediatric conditions than to those that occur also in the adult. There are no illustrations.

The treatment is dealt with in more detail. It is definite and practical although conservative in the sense that no whims of the authors have influenced the accepted standards of treatment. The authors attempt to separate the chaff of therapy from the wheat. They also discuss proprietary preparations and indicate such medicaments as are of doubtful value. Only the most reliable methods for handling each condition are described, and only those methods included with which the authors have had personal experience. The first part of the book is divided into two sections. One section of 339 pages is devoted to the outline diagnosis and detailed therapy of the various infants' and children's diseases according to the group of organs affected, such as the heart and blood vessels, glands of internal secretion, and skin. The second section, of thirty pages, describes therapeutic technique, such as methods of blood transfusion, baths, breathing exercises and inhalations. The second part of the book is divided into two sections. The first section, of 117 pages, constitutes a miniature pediatric pharmacopeia. Nearly all the practical drugs are listed with their synonyms, physical properties, uses, dosages and antidotes. Besides giving general rules for the dosages, four groups are considered: doses for infants, children from 2 to 5 years, school children from 6 to 12, and adults. The maximum dose for adults is also given. If a drug cannot be used for infants, the dosage for this group is omitted. The preparations of certain infant foods are also described such as butter-flour mixtures and albumin milk. The second section, of three pages, is devoted to toxicology. The book is a manual of therapy, not for the undergraduate student but for the practicing physician.

THERAPIE IN EINZELDARSTELLUNGEN. WISSENSCHAFTLICHE GRUNDLAGEN UND PRAKTISCHE ANWENDUNG. Herausgegeben von Prof. Dr. R. von den Velden und Priv. Doz. Dr. P. Wolff. Therapie der komplizierten Schwangerschaft. Von Professor Dr. Rud. Th. von Jaschke. Direktor der Universitäts-Frauenklinik in Giessen. Paper. Price 3.10 marks. Pp. 71. Leipzig: Georg Thieme, 1931.

The author sets forth in a precise and condensed form the treatment of the complications of pregnancy. The subject is divided into three parts including complications due to anomalies of the ovum and membranes, complications dependent on pregnancy per se and diseases of the mother complicating pregnancy. No new modes of therapy are revealed but the well recognized methods of treatment are described in detail, actual prescriptions of medication being frequently presented. The author recommends the conservative treatment for eclampsia, describing in

detail the alternation of morphine and chloral hydrate, which he describes as the Zwielfel-Stroganoff treatment. Retroversions in early pregnancy are not manipulated until the second half of the third month, when if the condition is still present, the cervix is brought down with volsella and the uterus replaced by forward pressure of a finger in the rectum. This is important to avoid incarceration. For the treatment of puerperal pyrexia, the author asserts that diet plays the most important part in determining the reaction of the urine. He presents complete lists of common foods, classified as to whether alkaline or acid. On the alkaline diet 4 Gm. of sodium bicarbonate is given three times daily, and on the acid diet 0.5 Gm. of methenamine three times daily. *Trichomonas vaginalis* vaginitis is treated by scrubbing the entire vagina with 1 per cent corrosive mercuric chloride followed by 10 per cent sodium bicarbonate in glycerin. When the condition is apparently cleared, cultures of *Bacillus bulgaricus* are implanted into the vagina. The book is comprehensive and precisely written and should be a valuable addition to the library of the student and the practitioner as well as of the specialist.

A TEXT BOOK OF ORGANIC PHARMACEUTICAL CHEMISTRY FOR STUDENTS OF PHARMACY AND PHARMACISTS. By Charles H. Rovers, D.Sc., Professor of Pharmaceutical Chemistry in the College of Pharmacy, University of Minnesota. Cloth. Price \$7. Pp. 676 with 50 illustrations. Philadelphia: Lea & Febiger, 1930.

The text primarily is a commentary to the United States Pharmacopoeia and the National Formulary V, elucidating the reactions involved in their chemical processes, along with other useful information. In the greater majority of cases methods for manufacturing tests for identity and quantitative estimations are given for the compounds, also a list of the official preparations into which the compound enters and a concise description of the preparation and their uses. The book contains a number of minor errors: under potassium bicarbonate, baking soda appears as a synonym (although in some countries this is known), while for sodium bicarbonate it is omitted, ammonium valerate is given the formula for the normal salt, while in the description it is stated as 'having a somewhat varying composition'. Furthermore, under thallium it is stated "never used in medicine" causing the reader to wonder whether the author is familiar with the current uses of thallium acetate in depilatories. The printing is good. It is to be recommended as a reference work in that the author has refrained from describing in detail the therapeutic uses of the compounds in such a volume primarily for pharmacists.

KURZES HANDBUCH DER OPHTHALMOLOGIE. Herausgegeben von F. Schueck und A. Bruckner. Band III. Orbita. Nebenhöhlen. Lider. Tränenorgane. Augenmuskeln. Auge und Ohr. Bearbeitet von M. Bartel, A. Birch-Hirschfeld, R. Cords, A. Linck, W. Lohlein und W. Meisner. Paper. Price 134 marks. Pp. 745 with 454 illustrations. Berlin: Julius Springer, 1930.

The third volume of this handbook appeared promptly as promised in sharp contrast to its big sister, the Graefe-Siemisch Handbuch. The first chapter of this volume is on disease of the orbit, by Birch-Hirschfeld. It follows in general the same chapter in Graefe-Siemisch by the same author but is abbreviated to 136 pages by the elimination of case reports and much of the bibliography. Like all of this author's work, the chapter is excellent, thorough and well worth careful perusal. The second chapter deals with anatomy and diseases of the nasal accessory sinuses and is written by Linck of Greifswald. Owing to the close relationship to the eye, such a purely rhinologic discussion occupies an important place in an all embracing ophthalmic textbook. It is interesting to note the definite stand of the author regarding the rhinogenic origin of retrobulbar neuritis, based evidently on extensive clinical experience. This chapter occupies 106 pages. Next comes Lohlein with 124 pages on the lids. This is a well written clinical chapter. The following chapter of 72 pages, by Meisner on the tear passages, is not of the same caliber and in many spots is too elementary for an advanced work of this type. The physiology of ocular movement is taken up by Cords in the next 50 pages. This is well done from the standpoint of physiology, physiologic optics and clinical application. Much miscellaneous information, scattered promiscuously throughout the literature, is compiled in this chapter which is well worth the attention of every ophthalmologist. The pathology of eye movements is written by the same author and is allotted 170 pages. It is on a par with the pre-

reading chapter. Due attention is given the work of English and American involutists as well as to the continental authors. For Anglo-Saxon tastes, the question of various types of strabismus could have been elaborated on somewhat more at length, but this is compensated for by the excellence of the work on muscle paralysis. This part is illustrated extensively and in a way that clarifies the well written text. It is not particularly easy to read but is well worth while reading. The last part of the text 79 pages is taken up by Bartels with a discussion of the eye and ear, particular attention being paid to myasthenia of various types. It is a valuable supplement. On the whole, this volume maintains the standard set by the two preceding volumes in every respect. Typographic errors are few, the illustrations are clean-cut, good and pertinent to the text, and the indexing allows of easy accessibility to facts.

L'ARTHRITE CHRONIQUE DE LA HANCHE Par L. Duvernay, medecin consultant a Aux les Bains. Paper. Price 40 francs. Pp 147 with 51 illustrations. Paris: Masson & Cie 1930.

This little book deals with one phase only of the arthritic syndrome, *namely*, involvement of the hip. The subject is discussed under the heads of simple arthritis, proliferative arthritis, ankylosing arthritis and arthritis deformans and therefore does not fully fall in line with the two main divisions of atrophic and hypertrophic arthritis generally accepted in this country as well as in England under the terms rheumatoid and osteoarthritis. Certain premonitory symptoms are stressed, which should be of some value to students of the subject, such as inguinal pain and the preservation of flexion, while abduction is difficult or impossible. Surgical treatment is briefly dismissed as usually inadvisable. Medical treatment is rather naively comprehended by recommendations that are free from any views but do not suggest an especially philosophic grasp of the subject of arthritis as a whole. There are many reproductions of roentgenograms which, as is so often the case, probably fail to do justice to the originals. The book is paper bound and rather heavy though well printed. There is something to be said in favor of the publication of small books in paper form at a lower price than is necessary for a bound volume.

ABDOMINO-PELVIC DIAGNOSIS IN WOMEN By Arthur John Walscheid, M.D. Director of Obstetrical and Gynecological Department of Broad Street Hospital. Cloth. Price \$12.50. Pp 1000 with 397 illustrations. St. Louis: C. V. Mosby Company, 1931.

This is designed chiefly for the postgraduate and the general practitioner, and for student reference. It is written solely for diagnosis. The first third of the book is concerned with general gynecology. The remainder enters into detailed consideration of especial diseases of the various organs. The author assumes the rather unique view that illustrations leave only a fleeting impression and advocates that they be used sparingly. A fairly generous number of drawings are found throughout his book. In addition to illustrations from other works there are many photo-micrographs, pictures of pathologic specimens, and a large number of somewhat unusual schematic and semi-diagrammatic drawings. Walscheid has a fluent style and an unusually extensive vocabulary. He tends somewhat to confuse the reader by long drawn out dissertations on various topics that present the personal views and theories of the writer and are of only passing interest to the average reader. Despite the graceful manner of presentation, the book is rather difficult to read without fatigue. Salient points are hidden and important diagnostic items are often omitted or accorded only casual mention. The author's attitude relative to important factors in diagnosis is often in contrast with generally accepted views. For example he describes the *cerviceros cervix* as hard, whereas fertility and bleeding are the commonly accepted pathognomonic features emphasized in the palpatory diagnosis of this disease. Although reference is made to some American authors of note on the whole there is a dearth of names of men who are widely known in this field. This is probably the only textbook appearing within recent years which has accorded only passing mention to the name of John Sampson in the discussion of endometriosis—an oversight that can scarcely be forgiven in an American text. The book is presented in an unusual book—one that reveals an enormous amount of labor and presents many unique and interesting views. On the whole, however, it leaves one with the impression that

there is a lack of fundamental scientific data to support the theories advanced and an absence of proper emphasis on essential features of diagnostic importance.

A DISEASE OF PARROTS COMMUNICABLE TO MAN (PSITTACOSIS) By L. L. Sturdee, O.B.E., M.R.C.S., and W. M. Scott, M.D. Medical Officers of the Ministry of Health. Ministry of Health Reports on Public Health and Medical Subjects No. 61. Paper. Price 2s. 6d. Pp 132 with illustrations. London: His Majesty's Stationery Office 1930.

This report considers the recent outbreak of parrot fever particularly as it affected England. There are sections on the history of the disease, its epidemiology, the clinical aspects and the pathologic anatomy. Dr. Levy Simpson participated in the preparation of three of these sections. The treatment of the disease with convalescent serum is considered rather too conservatively in view of the fact that at present this treatment is the only approach to specific treatment available. The section on etiology is by S. P. Bedson and G. T. Western. Mervin Gordon contributes an article on virus studies of psittacosis. The view that psittacosis is caused by a filtrable virus is favored. The report is a valuable contribution to the literature on parrot fever of especial interest perhaps to medical health officials particularly in the practical aspects, but of value to all students of this disease.

CO SIDERACIONES CLINICAS Y NOSOLOGICAS SOBRE EL DELIRIO DE INTERPRETACION. Tesis que presenta para su examen general de Medico Cirujano y Partero Por Edmundo Bauntello y Villa. Paper. Pp 159. Mexico 1930.

This thesis is begun with a presentation of a typical case of paranoia. It is followed by a general discussion of this mental disturbance which also takes the hallucinatory and schizophrenic paranoias into consideration. The monograph is well written but references to medical literature are too few.

MANUAL OF HOSPITAL MANAGEMENT FOR U. S. MARINE HOSPITALS By M. H. Foster, Medical Director, United States Public Health Service, U. S. Treasury Department, Public Health Service. Miscellaneous Publication No. 29. Paper. Price 65 cents. Pp 303. Washington, D. C.: Dept. of Defense Government Printing Office 1930.

The manual is exactly what the name indicates and as such is complete and without doubt valuable for the use of those having to do with the management of United States marine hospitals. Much of the material would apply equally well to civilian hospitals. It contains chapters on hospital organization and administration, management of medical and surgical ward, dietetics, laundry, grounds, buildings and mechanical equipment. The appendix contains instructions, formulas, recipes and menus not usually found in books on hospital management including directions for planting and care of evergreens on the hospital grounds.

THE EFFECT OF QUININE ON THE PRODUCTION OF GAMETOCYTES IN SUBTERTAN MALARIA By C. Russell Ames. Fellow of the Institute for Medical Research, Federated Malay States No. 2 of 1930. Paper. Pp 10. Kuala Lumpur: Federated Malay States Government Printing Office 1930.

Forty patients having gametocytes in their blood on admission to the hospital were given 2 Gm. of quinine hydrochloride daily and were observed for seven days or longer. A comparison of this series with another one consisting of forty patients treated similarly but without quinine treatment indicates that quinine does not affect the production of gametocytes. This conclusion is corroborated by a third series in which the gametocyte content of the patients' blood was estimated for several days before treatment and compared with the gametocyte content after treatment with quinine.

HAUPTBUCH DER GEISTESKRANKHEITEN Herausgegeben von O. H. Bumke. Band VIII. "Senie" Teil Teil 4. Supplement. Ein Beitrag zur Lehre von der Paralyse des Grosshirns. Ein Beitrag zur Lehre von der epileptischen Krankheit. Bearbeitet von A. H. Bumke. H. W. Grunke u. W. Fay. Paper. Price 6 marks. Pp 71 with 50 illustrations. Berlin: Julius Springer 1931.

This volume deals in particular with psychiatric disorders due to syphilis, arterio-sclerosis and senility. An abstract of the contents of course, cannot be given. It must be stated as has been done as each volume of this handbook has been reviewed that nothing as complete or as well done has ever appeared before and that each volume is invaluable.

DIFF AND CARE OF THE SURGICAL CASE. By Reynold H. Boyd, M.B. Ch.B. F.R.C.S. Clinical Assistant at St. Peter's Hospital for Stone. With an introduction by C. C. Choyce, C.M.G. C.B.E. F.R.C.S. Director, Surgical Unit, University College Hospital Medical School. Paper Price 5/- Pp. 106. London: H. K. Lewis & Company Ltd. 1930.

This is a handy manual concerning preoperative and post-operative care. After discussing a few general principles in regard to diet and the preparation of surgical patients, the author considers the various parts of the body and presents the salient features required in the treatment of a number of conditions affecting these. A portion of the book is devoted to the surgical care of children in general as well as conditions peculiar to childhood such as cleft palate, harelip, intussusception, congenital pyloric stenosis and idiopathic dilatation of the colon. The manual is far from complete. It is essentially an outline of generally accepted standardized principles and procedures concisely presented.

Medicolegal

Compensability of Pneumonia

(*Gallup v. State (Conn.)* 149 Atl. 118)

Galluzzo worked himself into a sweat one winter day, shoveling sand in the course of his employment, and immediately thereafter rode in the cab of a truck for some distance. This was repeated several times, until late in the afternoon he was taken home ill, cold, and sore in his back and legs. Pneumonia developed and he died. The compensation commission denied compensation to his widow on the theory that if the pneumonia was traceable to the employment it could be only through weakened resistance or lowered vitality, and that it therefore came within the provisions of section 7, chapter 307, Public Acts of 1927, the Workmen's Compensation Act, in part as follows:

A personal injury shall not be deemed to arise out of the employment unless causally traceable to the employment other than through weakened resistance or lowered vitality.

The order of the commission was affirmed by the superior court, and the widow appealed to the Supreme Court of Errors of Connecticut.

In two cases previously decided by this court, said the Supreme Court of Errors, compensation was denied where an employee, doing arduous work under abnormal weather conditions, contracted pneumonia and died. *Lumane v. Actna Brewing Co.* 91 Conn. 158, 99 Atl. 507, L. R. A. 1917D, 77; *Dupin v. Atlantic Refining Co.*, 98 Conn. 646, 120 Atl. 288. Compensation can be awarded only for personal injury and for occupational disease. Pneumonia cannot be an "occupational disease" within the meaning of the compensation act because an occupational disease is there defined as a disease peculiar to the occupation in which the employee is engaged, due to causes in excess of the ordinary hazards of employment. The claimant's right to compensation, therefore, must rest on proof that the deceased suffered a "personal injury," and this must be an accidental injury, which can be definitely located as to the time when and the place where the accident occurred (Pub. Acts 1927, chap. 307, sections 2 and 7), a localized abnormal condition of the living body directly and contemporaneously caused by accident' (*Lumane v. Actna Brewing Co.*, *supra*). The concurrence of accident and injury is a condition precedent to the right to compensation. It is possible to satisfy the foregoing definition of 'accident' by proof of exposure or other severe working conditions. As to contemporaneousness, however it appears quite conclusively, said the court that the pneumonia was not a contemporaneous result of the exposure, and that the only contemporaneous result which could have been caused was a weakened resistance and a lowered vitality, which cannot be the basis of any compensable personal injury.

The judgment of the commissioner in denying compensation was accordingly affirmed.

Evidence. Certainty of Expert Testimony.—The testimony of three physicians and a chiropractor, it was contended, invaded the province of the jury in that the witnesses were not asked for their *opinions* but for their *conclusions* as to whether

the accident caused the condition from which the plaintiff suffered and whether the injuries received in the accident caused her invalidism. The condition of the plaintiff, said the Kansas City Court of Appeals, was fully described by lay witnesses, whose evidence tended to exclude all other causes than the shock and injury received. From that evidence alone, the jury could find that her condition when she instituted suit resulted from the injury. There was no reason, therefore, why she should be deprived of the cumulative evidence of her physicians and should not avail herself of their opinion that her condition might or could reasonably and probably result from the injuries. The case is to be distinguished from *O'Leary v. Scullin Steel Company*, 303 Mo. 663, 260 S. W. 53, which in no manner limits or prohibits expert testimony as usually employed in a typical personal injury case. The *O'Leary* case, however, establishes an exception as to the weight and sufficiency of expert testimony on a given issue which may be proved only by the evidence of men of science. In such a situation the testimony must be explicit and positive, from cause to effect, that the stated injury did in fact cause the condition which followed.—*Stevens v. Westport Laundry Co. (Mo.)*, 23 S. W. (2d) 491.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Etiologic Factors in Carcinoma of Cervix.—A series of 220 cases of known carcinoma of the cervix has been compared by Smith with an almost equal number (202) of patients who have escaped the disease in the attempt to discover wherein the two series differ and with the hope of finding possible etiologic factors. Only patients that had had two or more pregnancies and had reached the age of cancer incidence have been selected for the control group. Knowing cancer of the cervix to be a disease of the poor, all of the control group were selected from this class of patients. Parturition with its resultant damage to the cervix is a generally accepted etiologic factor in cancer of the cervix. With the majority of cancer patients proving to be multiparous, this is not increase in importance with the number of pregnancies. The incidence of the disease is known to be higher among the poorer classes. Smith's study shows that there are apparently five additional possible factors: (a) Length of time between marriage and first delivery (more than two years being cited for increased statistics) with the suggestion of a possible field for irradiation as to contraceptives used. (b) Use of douches with compound solution of cresol. (c) More than one instrumental delivery. (d) Dry labor. (e) Untrailed cervical lesions as manifested by leukorrhea. One of these five possible factors

was not present more often in cancer patients than in the control group but, with the incidence of two or more of the factors present, the inequality in percentages of each group total progressively increased with the increase in number of factors. It can certainly be considered that when two or more of these additional factors are present with the known factors of parturition and poverty, the incidence of cancer of the cervix is increased. Menstruation is not shown to be a factor in carcinoma of the cervix. Possible factors suggested as fields for further investigation are: (a) Incidence of induced abortion, with especial reference to instrumentation. (b) Contraceptives types and duration of use. (c) Duration of labor. (d) Frequency of intercourse. (e) Observance of Mosaic laws.

Nephritis in Pregnancy.—Fifty-five cases of nephritis in pregnancy have been analyzed by Stieglitz. Nephritis in pregnancy is clearly divisible into three major classes: (a) The nephritis of pregnancy (syndrome of renal fatigue in pregnancy). (b) Eclamptic intoxication. (c) Preexisting renal and/or vascular disease exacerbated by pregnancy. A fourth group includes all those cases having other complications, such as cardiac disease, thyrotoxicosis, infections, and obstetric difficulties. Each of these groups is clearly defined and retains individual characteristics. The clinical syndrome, date and type of onset, associated changes, mode of therapeutic attack, and the prognosis differ in each group. Efficient therapy can be obtained only through proper recognition of the type of renal disease. Careful consideration of the causative factors of the renal injury and constant cognizance of the condition of the patient. It is not the disease that requires treatment but the patient.

Placenta Praevia at Johns Hopkins Hospital.—In a service of more than 36,000 admissions, Peckham says that placenta praevia occurred in 146 instances or approximately 1 in 250. In women admitted as emergency cases, the incidence is 1 in 30 whereas among those registered for prenatal care it is 1 in 500. It occurs once in every 98 deliveries in white women and once in every 158 in Negro women. The gross maternal mortality for the series was 10.96 per cent. It is higher in the Negro than in the white race, being 13.21 per cent and 9.68 per cent respectively. The maternal death rate from 1896 to 1910 was 19.23 per cent; since 1920 it has fallen to 8.64 per cent. In 57 cases of the marginal type there was only 1 death (1.75 per cent). 14.75 per cent of the cases of the partial type terminated fatally, while central placenta praevia gave a mortality of 21.43 per cent. The mortality was 5.36 per cent when the initial examination revealed the woman to be in good condition. This figure rises in the group classed as "fair" and when the situation was deemed ominous on admission the mortality reached 36.84 per cent. In 33 women admitted with a pulse below 90 there was not a single death. In 17 women admitted with the cervix closed there was not a single death. The highest maternal mortality (25.53 per cent) occurred in the group delivered immediately after admission. This group included cases of accoucheur force, widely dilated cervix, with bleeding throughout several hours of labor. There was not a single death among 35 women who were delivered not less than twelve hours after admission. Concerning the maternal mortality from the point of view of duration of pregnancy, the rate was 4.55 per cent when the pregnancy ended prior to the last lunar month whereas it was 15.58 per cent in those patients who were at or near term. A comparison of the maternal death rate according to the weight of the child delivered shows a higher figure at less than 5.5 lb. exceeds 2500 Grs. The mortality rate was 4.55 per cent at birth weights as against a much higher one at the full term. The mortality was highest in women who had had to or more previous pregnancies, 23.08 per cent. The highest mortality occurs in women aged 40 or more. Only 1 death occurred from a case of Hemorrhage was the most important factor in 13 cases. One woman died of a fatal embolism and 11 of surgical shock, the result of operative procedures being advised. In 6 of the 13 deaths due to bleeding the condition of the patient on admission was desperate. Only 1 of the cases died directly the responsibility of the doctor, the other 5 per cent falls to 5.49 per cent. The gross maternal mortality was 7.81 per cent. This is due partially to the large number of emergency admissions—10.92 per cent of all—146 cases.

2 500 Gm. Considering only those babies weighing 2 500 Gm or over, where the fetal heart beat was present on admission, the mortality falls to 38.71 per cent.

Arsenic Content of Placenta Following Arspenamine Therapy—Arsenic determinations were made by Eastman on twenty one human placentas from patients who had been receiving prenatal arspenamine therapy. After ten placentas had been analyzed it was thought that the results would be more significant if the placentas were divided into fetal and maternal portions, and each portion analyzed for arsenic in the last eleven placentas studied this procedure has been carried out by a technique to be described shortly. Following antenatal arspenamine therapy, arsenic is retained by the human placenta over periods as long as fifteen days after the last treatment. The duration of the retention is conditioned in part by the number of weekly injections the patient has had, a definite cumulative retention of arsenic being manifest. The retention of arsenic by the human placenta occurs chiefly in the fetal portion which often contains three or four times the quantity demonstrable in the maternal part. The storage of arsenic by the human placenta and particularly its greater concentration in the fetal part may be an important factor in the beneficial action on the fetus resulting from arspenamine therapy.

Coordination of Uterus in Labor—Two cases of asymmetrical contractions of the uterus in labor are reported by Rudolph and Ivy. These cases raised the question of the mechanism concerned. A review of the embryology, comparative anatomy and physiology of the uterus shows that it has a bilateral origin and that the two halves, except where fused, act more or less independently. On fusion, a correlating mechanism becomes manifest. A type of coordinated activity manifested by the postpartum uterus of the dog has been studied. An extrinsic and an intrinsic mechanism has been discovered, one resident in the uterine wall and the other in the uterovaginal ganglions, the former being the most important, and it has been found that the dog's uterine motor mechanism in situ manifests the phenomena of refractory period and "summation." On the basis of a functionally defective coordinating mechanism, the irregularity in the uterine motility, obliquity of the uterus in the two cases observed, is explained and a basis for the explanation of other types of abnormal motor activity is offered.

Rhabdomyosarcoma of Corpus Uteri—A rare case of rhabdomyosarcoma of the corpus uteri is reported by Shapiro. It arose subserously, as a simple heterologous tumor, and apparently within a preexisting myoma. It developed from embryonic rests of striated muscle cells displaced in the course of the downgrowth of the wolffian duct.

Aniline Poisoning in New-Born—In the thirteen cases reported by Weinberg the poisoning resulted from the baby's body being wrapped in clothing freshly marked with the hospital identifying lettering. In practically all the cases the printing was found to be in contact with some part of the babies' bodies, in fact, definite staining was found on the skin of eight of the thirteen babies. The immediate measures that were undertaken to eradicate the danger were as follows: All new linens were removed from contact with the infants. The babies were thoroughly washed with alcohol or ether to remove all the print stains and were then clothed in linen that had already been boiled and washed. A mixture of oxygen and 5 per cent carbonic acid was administered to babies as needed. All babies were carefully observed every few minutes so that immediate measures could be undertaken if a patient suddenly became worse. The symptoms manifested were as follows: The pulse in every case became very rapid but maintained its regularity and rhythm. There was no variation of the temperature from normal. Respirations were greatly accelerated but continued regular. Cyanosis was marked in practically all cases. Cyanosis was most evident on the lips and eyelids. All suffered from anorexia. The degree of apathy was pronounced in practically all cases. The response to stimuli was decreased in every instance. Only one case showed what could be considered a convulsive seizure. The cry was decreased in strength in every case. The extremities tended to be cold and cyanosed in all cases. The subsequent course showed complete recovery in every case within a period of from twenty-four to seventy-

two hours, without any observable harmful effects. The mixture used for marking contained phenol, levulic acid, aniline, and induline dye (spirit soluble).

Differential Quantitative Tuberculin Test—A differential quantitative intracutaneous tuberculin test using both human and bovine tuberculin in parallel series is described by Blair and Calland. The dilutions used are so chosen that basic dilution is of a potency comparable to that of the Mantoux test, and the series extends to dilutions sufficiently weak to exclude all but the truly hypersensitive tuberculin reactants. These dilutions, with tuberculin of a potency usually found in commercial samples, range from 1:10,000 to 1:10,000,000. Inclusion of both human and bovine tuberculin diminishes possibility of missing occasional cases, which might be overlooked when only one type of tuberculin is used. A total of 471 cases is reported comprising children and adults, tuberculous and nontuberculous. Of 121 tuberculous cases, 90.9 per cent reacted positively to the diagnostic dilutions, and 9 per cent gave a negative reaction. Of 350 nontuberculous cases, 92.5 per cent gave a diagnostically significant negative reaction. 74 per cent reacted to the diagnostic dilutions. Of 23 tuberculous cases tested with both human and bovine tuberculin, 4 (17.3 per cent) would have been missed had only one type of tuberculin been used.

Tuberculous Infection in Children—Dickey and Seitz made 3,500 intracutaneous tuberculin tests on children. The incidence of tuberculous infection, as shown by such tests, increases with age. The incidence for the vicinity of San Francisco is 46.6 per cent at 14 years, about the beginning of adult life. This rate is compared with those obtained by similar methods in other communities. The authors assert that the Pirquet tuberculin test should not be employed in studies of this kind, since it gives erroneously low figures.

Sodium Amytal in Advanced Tuberculosis—Cherry reports sixteen cases in which he administered from 3 to 5 grains (0.2 to 0.3 Gm.) of sodium amytal intramuscularly for hypnotic and analgesic purposes. It does not produce local pain or tissue change even in the most emaciated persons. Physiologically,

however within fifteen minutes after injection the patients begin to experience mild cerebral depression so that apprehension and muscular tension seem markedly restrained. The thalamus, along with the medulla, seems to be markedly influenced so that pain and sensory reflexes are restrained. These actions of the drug grow in intensity for a period of three or four hours and are prolonged over a period of from eight to twenty-four hours according to the size of the dose. In no instance has Cherry seen complete narcosis approached when the dose did not exceed 6 grams (0.5 Gm.). Smaller amounts do not produce sleep from which the patient cannot be awakened easily and quickly to clear consciousness. Occasionally sleep is not without excitement causing the patient to talk and move about in bed. The blood pressure or respiratory cycle is not appreciably disturbed. Gastro-intestinal motility is not disturbed, although almost every case presenting abdominal pain experienced marked alleviation.

Heredity of Carcinoma in Man.—Putting all of the observed facts together, Warthin says that the following data are available concerning hereditary susceptibility to neoplasms: multiple incidence of neoplasms in family generations; dominant inheritance of neoplasms in some families; recessive inheritance of neoplasms in some families; "Durchschlag" inheritance in some families; appearance of neoplasms at an early age in the later generations; appearance of neoplasms independently of extrinsic factors; multiple incidence of neoplasms affecting the same organ or system; multiple incidence of neoplasms affecting different organs or systems; varying degrees of resistance or susceptibility to neoplasms within the same family generation; symmetrical tumors in different members of the family; and the occurrence of symmetrical neoplasms in the same organ and part of the organ or its mirror image in identical twins. It seems to Warthin that the best interpretation of these facts rests on the assumption of at least four hereditary factors: the normal constitution resistant to blastoma; the pathological blastoma constitution; the normal resistant organ or tissue; and the pathological organ predisposition to cancer. Each of these factors must be composite; no one is a simple unit factor in the mendelian sense. In some families the four factors appear to be inherited as genes. The individual who has a single case of cancer developing in two or three generations of his family has not great cause for worry. But the individual who has a family history of the multiple incidence of cancer in several generations should take heed.

Association of Cholecystitis with Cardiac Disorders.—Of 109 patients with chronic cholecystitis studied by Schwartz and Hermann 63.3 per cent had associated myocardial disease or which 56.5 per cent were combined with obesity. Of the entire group 52.2 per cent were obese, 68 per cent of the obese patients had Leitz disease. It is deduced from data obtained in this study that the infected gallbladder and obesity are equally responsible for the myocardial damage of patients with chronic cholecystitis.

Cessation of Auricular Paroxysmal Tachycardia by Use of Calcium.—A series of three cases of simple tachycardia is reported by Wolfe and Belleit with electrocardiograms in which the paroxysms were immediately terminated by the

intravenous use of calcium. It is believed that this is a therapeutic measure which while not successful in every instance is well worth trying when other methods have failed and when the length of the attack is dangerously prolonged. There is some evidence that administration of calcium by mouth between attacks tends to lessen the number of paroxysms.

Intestinal Flora in Psoriasis.—Schwartz et al. report that no evidence has yet been found that would seem to indicate any connection between the numbers and types of bacteria vegetating in the human intestine and the development of psoriasis.

Reactions of Skin to Intradermal Injection of Arsphenamine.—Intradermal tests with arsphenamine preparations have been carried out by Moore et al. in four groups of persons: (1) thirty-six normal controls, (2) sixty-one patients with syphilis most of whom had received therapeutic injections of arsphenamine without the occurrence of reactions of the dermatitis group, (3) nineteen patients with allergic instability (hay-fever) and (4) thirty-five patients who had suffered from postarsphenamine dermatitis. In about 60 per cent of normal persons a delayed reaction, "flare-up" develops at the site of intradermal injection after an incubation period of from three to four weeks. This has been interpreted as evidence of sensitization of the skin to arsphenamine. In a smaller proportion (44 per cent) of syphilitic patients under treatment, similar reactions develop which are less severe and extensive and which appear earlier (in from two to three weeks) than in normal controls. This reduction in incidence and severity and the shortening of the incubation period are attributed to the desensitizing effect of the previous or simultaneous intravenous administration of arsphenamine. In all except one of a series of patients with hay-fever tested, much more violent and severe reactions developed than in normal or syphilitic controls and these reactions appeared earlier (in from one to two weeks) than in either of the control groups. This is interpreted not as sensitization to arsphenamine but as probably due to local auto-inoculation of the sensitized patient with his own antigen (pollen) in an inflamed area (Auer's phenomenon). In thirty-five patients with postarsphenamine dermatitis severe postarphenamine reactions appearing much earlier (in from two to seven days) than in any of the other groups occurred in 70 per cent of those who had had the exfoliative type of dermatitis and in only 11 per cent of those who had had other types of rash. A negative skin test in postarsphenamine dermatitis does not indicate the absence of hypersensitivity to arsphenamine since many reacting patients had often had repeated generalized reactions on attempts to administer therapeutic doses of the drug.

Results from Use of Gold Compounds.—Report is made by Driver and Weller of a series of patients treated with gold compounds. In 25 cases of lupus erythematosus gold therapy was used in 10 cases and in 15 cases of lupus erythematosus in 10 cases. A general review of the

developed with fever, prostration, hemorrhages from the vagina, total loss of heming, and icterus. It is believed that death resulted from acute yellow atrophy of the liver due to idiosyncrasy to gold.

Nonspecific Therapy in Dermatology—Wright asserts that nonspecific therapy is of definite value in the treatment of a number of diseases of the skin. Autohemotherapy may prove of distinct value in the treatment of psoriasis, as an adjunct to local therapy, and in lessening the activity of the eruption it is often a distinct aid in the treatment of patients with chronic urticaria. Milk preparations are of value for the immediate treatment of furunculosis and carbunculosis. Pruritus of idiopathic origin or severe pruritus accompanying a dermatosis may in some instances be quickly and effectively relieved by the intramuscular injection of a milk protein. In eczema, acne and psoriasis milk preparations have proved disappointing. Nonspecific vaccine therapy is of some value in the treatment of psoriasis. The use of a *Streptococcus fecalis-Bacillus coli* vaccine is recommended for office use when a mild nonspecific action is desired in psoriasis. Injections of turpentine have proved of value in the treatment of trichophyton infections and certain bacterial infections.

Coronary Thrombosis—Eight cases are reported by Levy as exemplifying mild forms of coronary thrombosis. The records of these patients appear to define a distinct clinical group, characterized chiefly by the relative youth of the patients (all being less than 50 years of age) and the rapid rate of recovery, both subjective and objective. A critical analysis is made of the various features, and some of these are discussed. Because the clinical picture is at times atypical, it is believed that this condition frequently is not recognized. Although a rapid rate of recovery tends to indicate a favorable outcome of the immediate attack, accurate prognosis as to the liability to recurrence and life expectancy is extremely difficult.

Erythema Infectiosum—An epidemic of ninety-seven cases of erythema infectiosum occurring in Branford Conn., is reported by Lawton and Smith. Experimental work the results of which were entirely negative, is cited. The epidemic in Branford was similar in all respects to previously reported epidemics of erythema infectiosum. The characteristic features of the disease are the rash, its distribution, the evanescence, the relatively long duration and the absence of other symptoms. It seems to be a distinct clinical entity, and all evidence points to its being transmitted from person to person although the exact mode of transmission and the etiology of the disease are unknown.

Leukemic Changes of Gastrointestinal Tract—From sixteen cases of leukemia, eleven myelogenous and three lymphatic, were studied by Boikar with reference to the gastro-intestinal involvement. Nonspecific changes were found in nine cases (acute myelogenous leukemia, consisting of hemorrhages, ulceration and secondary inflammatory processes. In two cases (acute myelogenous leukemia) there were no changes. Specific changes were found in two cases of acute myelosis consisting of infiltration of the appendix and an infiltration of Peyer's patches, respectively. Specific changes were found in one case of chronic lymphatic leukemia. The stomach was enormously enlarged with huge convolutions on the inner surface giving it a brain-like appearance and the intestines were beset with plaques and polypus-like infiltrations. In a review of the literature a other such case was not discovered. The case was found however to parallel exactly those described as leukemic lymphadenoma or pseudoleukemia gastro-intestinalis. From these facts it is concluded that the leukemic and leukocytic leukemias are fundamentally identical. In further support of this conclusion a last case is described in which an aleukemic lymphadenoma terminated as an acute leukocytic lymphadenoma.

Hypochromic Anemia with Achlorhydria—This type of anemia, according to Waugh is so readily confused with other hypochromic anemias that it often is not recognized. Many physicians are satisfied to rule out pernicious anemia carefully and then to rest content on a diagnosis of "secondary anemia" without further investigation or distinction. A smear is made and a blood count is done, no megalocytes are found, the color index is low and at once all interest in the anemia disappears. This condition never reaches the severity of pernicious anemia and hence is more readily passed over. The patients do not look as sick as they really are and one is greatly surprised to find the hemoglobin so low. They show so favorable a picture, on physical examination except for the anemia and they complain so little except of fatigue, lassitude and perhaps palpitation on exertion that one is inclined to consider them hypochondriac. Moreover, although the anemia is persistent, it rarely, if ever, increases to a sufficient degree to cause the death of the patient. All of the author's cases have occurred in women, from 35 to 45 years of age, though occasional cases in younger and slightly older women occur. No case occurred in a woman after the menopause. Physical examination reveals comparatively few abnormal signs. The red blood cells are only moderately reduced in number, figures between 3,500,000 and 4,000,000 being most common. On the other hand, the hemoglobin is relatively low, ranging from 30 to 60 per cent. Consequently, the color index is often extremely low, and the hemoglobin concentration is markedly reduced. In typical cases there is a moderate leukopenia. The blood plates are somewhat reduced in number though low figures suggesting an approaching hemorrhagic diathesis were not observed. Finally, the serum is inclined to be a rather pale yellow with a faint or moderate green tinge. To summarize, there is a marked low color index, a hypochromic anemia, with evidence of deficient erythropoietic and leukopoietic myeloid activity. Moreover, the anemia is not hemolytic. The anemia in these cases is extraordinarily persistent. Following pregnancy there is apparently some improvement, but a marked anemia persists. The patients invariably complain that they dislike taking iron and that it does them no good. Arsenic possibly causes an improvement in the subjective symptoms but no appreciable alteration in the blood picture. These cases do not respond to liver therapy as do those of pernicious anemia. The benefit of transfusion is only temporary, and the blood rapidly falls to its previous level. In fact the persistence of the anemia and its tendency to maintain a constant level for months in spite of all manner of therapy is one of the striking characteristics of the disease.

Polycythemia Vera and Chronic Pulmonary Disease—Four cases of polycythemia and chronic pulmonary disease with blood volume comparable to that seen in polycythemia vera are reported by Barker. Treatment in these cases was by the administration of phenylhydrazine hydrochloride, there was a definite reduction in the blood volume with clinical subjective and objective improvement. Because of the high blood volume and a good response to treatment by destruction of blood these cases are considered as polycythemia vera with associated or complicating pulmonary disease.

Potassium Content of Heart.—The results of analyses made by Scott of thirty-two hearts for potassium and sodium do not seem to indicate that there is on an average any appreciable difference in the amount of these elements in hearts from edematous and from nonedematous patients. The water content is practically the same for the two categories. There is considerable variation in the amount of potassium and sodium in hearts, regardless of whether the disease processes from which the patients died were or were not productive of edema. The percentage of sodium may be greater than that of potassium and vice versa without any apparent relation to disease. Demonstration of potassium in cardiac tissue indicates that the larger proportion of the salts is contained in the fluid bathing the muscle cells and that they are rather uniformly diffused throughout the protoplasm.

Terminal Hypoglycemia.—Blood chemistry determinations have been made by Schmidt before, at and one hour after death on thirty-three nondiabetic patients dying in the hospital. Among these thirty-three unrelated cases, twelve cases or 36 per cent showed low terminal blood plasma sugars ranging from 28 to 75 mg per hundred cubic centimeters at the moment of death. In a number of cases it was demonstrated that this pronounced and suggestive hypoglycemia existed before death as well as at death. Only a slight decrease was noted in the blood sugar during the hour immediately following death although there were two noteworthy exceptions in which the sugar of the heart blood decreased from 154 to 50 mg and from 166 to 33 mg. The blood urea frequently increased rapidly just prior to death, but little change took place after death. Frequently there was a terminal rise in amino acid nitrogen which continued to increase somewhat after death. The carbon dioxide combining power of the plasma decreased somewhat shortly after death, but the chlorides remained unchanged.

Liver Extract for Pernicious Anemia.—One hundred and one patients with typical pernicious anemia were treated by Zerfas with potent fractions of liver. Sixty-one of these patients were given adequate daily amounts of a standardized fraction of liver. The results obtained relative to the production of reticulocytes are in accord with those reported by Minot and his associates. The maximum number of reticulocytes produced at the peak of their increase was influenced by the level of the red blood cells before treatment was begun and by the daily amount of potent extract of liver ingested. In uncomplicated cases the amount of extract (approximately 12 Gm) derived from 300 Gm of liver produced a slightly submaximal number of reticulocytes on the day of the peak; however the number of red blood cells produced at the end of one month was essentially the same as that produced when larger daily amounts of extract (that derived from 400 to 1,000 Gm of liver) were given. The average gram in red blood cells at the end of one month's treatment for the entire series of 101 patients bore an inverse relation to the level of the red blood cells before treatment was begun. In the patients whose red blood cell counts were below 5 million per cubic millimeter of blood before treatment, the count reached approximately a level of 35 million at the end of one month. The number of reticulocytes produced at the peak of their rise combined with information relative to the rate of red blood cell production for the first month of treatment seems a useful means of determining the potency of fractions of liver.

Bacillus Pyocyaneus Meningitis.—The case presented by Virelizier et al is said to be of especial interest because of the following factors: (1) primary *Bacillus pyocyaneus* meningitis with minimal systemic and localizing symptoms and with no recognized portal of entry; presumably the infection entered through the lymphoid tissues of the upper part of the respiratory tract or through similar tissues of the digestive tract such as the Peyer's patches; (2) absence of the three recognizable etiologic factors found in other cases in the literature namely trauma to the brain or spine, lumbar puncture or *B. pyocyaneus* septicemia; (3) seemingly good therapeutic results from decompression; (4) evidence of the local character of the infection as seen in the development of agglutinins in the spinal fluid but not seen in the blood stream; and (5) rapid recovery in contrast to the two other general types of cases heretofore described, rapid and fatal progression, a long drawn out recrudescence illness, and evidence that even in *B. pyocyaneus* meningitis one is dealing with an organism of relatively low virulence.

Maldevelopments of Auricle, External Meatus and Middle Ear.—Fraser states that the condition of microtia and mental atresia is not rare. It occurs more frequently in males than in females and more often on the right side than on the left. Unilateral cases are more common than bilateral. In rare instances the condition occurs in more than one member in a family. Facial paresis, maldevelopment of the mandible, facial hemiatrophy and other congenital deformities are not infrequently noted in association with microtia and mental atresia. Hearing tests usually show the results obtained in lesions of the sound-conducting apparatus but even in bilateral cases the human voice is, as a rule, heard well enough to allow the patients speech to develop. Functional examination by means of the rotation tests shows as a rule that the vestibular apparatus is normal. Operation should be performed in unilateral cases only when otitis media and mastoiditis are present on the affected side. In other unilateral cases the improvement in hearing is not sufficient to justify operation. In bilateral cases operation is called for only if the deafness is marked and if roentgenograms and functional examination show that the labyrinth is healthy.

Radical Mastoid Operation.—A review by Smith of the best surgical procedures advocated for relief from chronic antral suppuration during the last twenty years reveals the fact that in the early part of this period a large majority advised the radical operation. Later there was a gradual change with a progressive improvement in the sentiment toward the various modifications of the radical operation. The danger at present is that the pendulum may swing too far in that direction. During the whole period there was always the possibility of being misled by the overenthusiastic advocates of the operation, as well as by those who professed to believe that the radical operation is never indicated. The old adage that the point of safety lies somewhere between the two extremes applies here. The temporal bone shows a wide variation within its normal anatomic limits from the small infantile type with a complete absence of cells or mastoid cavity to the large pneumatic bone with an extensive cellular development and mastoid cavity. There must necessarily be a marked variation in the degree of bone destruction encountered in the different cases. There may be an extensive destruction of the drum membrane and ossicular chain with little or no involvement of the mastoid structures, or the reverse may be true with an extensive destruction in the mastoid and the ossicular chain intact. It is evident that a different type of operation is indicated in these cases. It will therefore be impossible to employ an one-particular operation in all cases and it becomes a question of adapting the operation to the case. When there is little or no destruction of the ossicular chain some otologists prefer to lower the posterior wall of the ossicles to remove and cut a flap. In these cases the author prefers to perform a complete simple mastoidectomy, and the aditus wide expose the antrum, remove all the granulation tissue and treat the wound as a simple open wound. Lowering the wall or cutting a flap. Occasionally the granulation removed from the antrum and obtained a dry ear. When the malus and incus require removal and the posterior wall of the canal is intact, he performs a new radical operation by complete removal of the diseased structure in the mastoid and

middle ear without removing the wall of the canal. In this manner the cavity and flap of the radical operation are avoided and the hearing results are improved. For the extensive infections in which these modifications are not adequate, a complete radical operation should be performed. The radical operation has a definite place in surgical otology, one that can never be replaced. Its technique makes it possible to obtain the most complete excitation of the diseased structures. There will always be certain cases which demand this operation; there will be others in which a less extensive operation will suffice. The fact seems to be definitely established that both the radical operation and some of the more conservative procedures have their selective indications. In many instances the absence of symptoms other than the foul smelling discharge makes it impossible to determine the extent of the necrosis before operation; on the best policy would seem to be to allow the degree of bone destruction in the individual case to dictate the type of operation and to be able to perform the one that seems to promise the best results.

Are Tonsillar Recurrences Entirely Due to Faulty Operative Technique?—Leshm and Pearlman call attention to extratonsillar tissues which often contain lymphoid tissue embedded in their layers and which are frequently neglected by many in routine tonsillectomy. Furthermore, following tonsillectomy in which the main tonsil mass is apparently completely removed in those instances in which the pharynx are well developed sites for possible future lymphoid hypertrophy are still left in nearly 50 per cent of all cases. Whenever these pharynx are well developed and this applies particularly to the pharynx triangularis, they should be removed separately. There is no method of tonsillectomy that insures the patient positively against the future recurrence of lymphoid tissue at the site of operation. This statement is based on histologic evidence of the presence of lymphoid tissue surrounding the immediate tonsillar site and is confirmed from embryologic evidence that indicates that the tunica propria of the mucosa in this entire region contains lymphatic structures with marked tendency toward hypertrophy. Epithelialization of the raw operative area occurs as the result of the surrounding mucosa with its tunica propria, growing down into it and retaining in its new site the ability to form lymphoid structures. The occurrence of hypertrophy in some instances and its absence in others is due to constitutional and individual factors as yet not known.

Subcutaneous Mixed Tumor of Face not Associated with Salivary Glands—Brunschwig reports a case of subcutaneous mixed tumor of the face. According to the literature, these are uncommon. Since macroscopic diagnosis is not possible, a routine microscopic examination of all subcutaneous nodules removed from the face at operation would, no doubt, reveal a much greater incidence of this condition. Mixed tumors are potentially malignant and when present should be treated as such by thorough excision and prophylactic irradiation of the site occupied by the neoplasm. Since, therefore, many apparently benign nodules about the face may be potentially malignant neoplasms, their removal is recommended on the slightest pretext.

Roentgen Diagnosis of Disease at Base of Skull—For a general survey of the main structures at the base of the skull, Pomeranz considers two views necessary: one in the frontal direction and the other in the sagittal direction. The view taken in the frontal direction will, as a rule, disclose the changes of the sella, the general type of the skull and the thickness of the flat bones and their digital impressions. It sometimes occurs that the anterior clinoid processes are obscured by each other, then another view taken in a slightly (5 degrees) inclined position is necessary to separate them on the plate. The sagittal view should be obtained so that the central ray takes the direction of the German horizontal, i. e. the imaginary line connecting the upper walls of the external auditory canal with the lower orbital margin. The sagittal view may be taken in either the anteroposterior or the posteroanterior direction. In this view, if properly taken, one will see the pyramids in the lower third of the orbits, the foramen rotundum, small wings, large wings as a part of the orbital wall, superior orbital fissure, lamina papyracea, ethmoid bone and cells and often the sphenoid sinus. These two views will give a good general survey of the base of the skull. Of the numerous special views cited, three are par-

ticularly important. 1 The basal view of the middle fossa (Schuller), which should be taken in the submentobregmatic direction. If the patient cannot assume this position, this view can be taken in the opposite direction. In such a case the part of the middle fossa is obscured by the shadow of the mandible. In this view the main structures of the middle fossa are visualized: the foramina optica of the pyramids, sphenoid sinus, carotid groove, clinus and base of the pterygoid process (tumors of the nasopharynx). 2 The Stenvers view of the pyramids. The central ray is perpendicular to the longitudinal axis of the pyramids. This view gives a general survey of the pyramids and the outline and details about the inner ear, one can discern the semicircular lateral and superior canals, vestibulum cochlear, internal meatus and apex of the pyramids. Often this view has to be supplemented by Schüller's and Mayer's view of the mastoid part and of the tympanum. Mayer's view is taken in such a manner that the central ray is parallel to the longitudinal axis of the pyramids, aiming at the external auditory canal. It gives a good view of the tympanum, sigmoid sinus, antrum mastoideum and cells. Schüller's view is the routine lateral view of the pyramids. 3 The oblique view of the orbit by Rhese, modified by Gorkin. This view visualizes the optic canal. It is of diagnostic value only in selected cases. All the views described are necessary for visualization of the base of the skull. For the sinuses, particularly the maxillary sinus, the visualization of which was poor from the diagnostic standpoint, Mayer used the craniocentric view of Lisenfeld. This view projects the sinuses downward on the plate, partially distorting them. It has, however, the advantage that all the bony structures of the base of the skull (particularly the pyramids), which otherwise obscure the sinuses are projected downward. In the author's opinion it is not advisable, for several reasons, to use the Bucky diaphragm in the diagnosis of disease of the skull. The structure of the bones is coarse in comparison with its appearance in plates taken without the Bucky diaphragm. With the diaphragm in the special positions that are so important for diagnosis, roentgenograms cannot be taken on account of the excessive angulation of the central ray to the grids. It is also not advisable to use large distances and large cones in this work. The large distances will make one's interpretation of the film much more difficult; with large cones, the roentgenograms will not be sharply defined owing to an excessive amount of secondary rays. The use of small cones is best. It is also important to study a film with a skull in one's hand, first acquainting oneself with the method of projection used in the individual view.

Effect of Epinephrine and Ephedrine on Nasal Mucosa—Fox performed two series of experiments on rabbits to determine whether solutions of ephedrine and epinephrine, which are frequently prescribed over a long period in chronic nasal obstruction, are deleterious after long usage. He found that ephedrine hydrochloride in dilutions of 1:50, when sprayed daily over the mucous membrane of rabbits for three months caused little injury if any, to the tissues. Epinephrine chloride in dilutions of 1:1,000, when sprayed daily over the mucous membrane of rabbits for three months, caused considerable injury of these tissues.

Congenital Syphilis of Suprarenal Gland—The suprarenal glands from some 250 cases of congenital syphilis were examined by Fite. In only about 40 of these was there any abnormality whatever of the cellular structure of the gland to be observed, but some of the latter showed most striking changes attributable to syphilis. About half of the cases have been in still born infants. Most of the other subjects had died in the first month or two of life, and the oldest had died at 7 months of age. In none of these 250 cases, nor in some 150 others which defied microscopy on account of poor preservation, were any macroscopic gummas of the suprarenal gland seen.

Carcinoma of Stomach in Seventeen-Year-Old Girl—The patient whose case is reported by Marble was a girl aged 17 when first seen. The total duration of the disease from the onset of symptoms was about thirty-three months; the length of time after partial gastrectomy was twenty-two months.

Fixed Paralytic Obliquity of Pelvis—Fixed obliquity of the pelvis, as contrasted with obliquity due to actual shortening of a leg, Mayer says, is caused by a contracture of the structures connecting the pelvis and the thigh or the pelvis and the spine. It is characterized by the fact that when both legs are held parallel to the median line of the body, it is impossible to square the pelvis, even when the patient is in the recumbent position. Its practical significance is due to the apparent difference in the length of the legs which it causes. The type may be distinguished (1) due to contracture of the abductors (2) due to contracture of the adductors, (3) due to contracture of both abductors and adductors, (4) due to contracture of spinal and abdominal muscles, and of the quadratus lumborum (5) combinations of groups 1, 2 or 3 with group 4. The deformity can be corrected in the early cases by a push and pull apparatus, in the more advanced cases by suitable division of the contracted structures, coupled with stabilizing procedures to prevent recurrence of the deformity.

Low Back Pain—Analysis of statistics made by Miltner and Lowendorf show that the causes for low back pain in order of relative importance are (1) arthritis (1,350 cases), (2) sacro iliac sacrolumbar and combined sprains (525 cases), (3) muscle strain (100 cases), (4) lumbar myositis (25 cases), (5) other unusual conditions, as spondylolisthesis fractures of the transverse processes, fractures of the articular facets, undiagnosed fractures of the vertebral bodies and Kummell's kyphosis (50 cases). The study is concerned chiefly with low back pain due to sacro iliac, sacrolumbar or combined sacro iliac and sacrolumbar sprain (525 cases). In well over 50 per cent of the cases symptoms persisted into the chronic stage. Especially in the postural and occupational group were the symptoms found to continue over a period of years. Eight cases (15 per cent) had a definite psychoneurosis which was entirely

responsible for the pain. Certain symptoms, such as the radiation of the pain and the posture assumed, seemed to bear a definite relation to the type of sprain. The sacro iliac cases were more apt to have sciatic radiation (64.1 per cent as compared with the sacrolumbar cases, 21.9 per cent). Radiation into the areas of the lumbar nerves was present in 7 per cent of the sacro iliac cases and in 3.4 per cent of the sacrolumbar sprains. Pain in the course of the superior gluteal nerve was present in 6.1 per cent of the sacro iliac and in 2.6 per cent of the sacrolumbar cases. Concerning the posture assumed by the patient the unilateral sacro iliac case frequently showed a contralateral tilt or position of relief (24 per cent). A smaller proportion of unilateral sacro iliac cases showed a list to the same side as the sprain (homolateral 8 per cent). In explanation of the contralateral list, the patient leans to the opposite side to relieve the strain on the affected joint. Homolateral list is usually seen when there is an associated sprain on the same side as the pain. Trauma posture and occupational factors are the most important considerations in the etiology. In the chronic cases, i. e., those in which the symptoms persist over six months, the differentiation from chronic arthritis becomes very difficult. The differential diagnosis between sacro iliac and sacrolumbar sprain is based on (a) local points of tenderness which are anatomically separate, (b) localization of the pain (subjective), (c) the use of special tests as the Laguerre Goldthwait and Grienslen tests, straight leg raising and forcible compression of the iliac crests. Roentgen observations are not particularly important in the differential diagnosis and can be used only as confirmatory evidence after the essence of the treatment in the acute cases is complete and sufficient rest. Supports, belts, casts, braces, recumbency and traction may be used in the chronic cases. Physical therapy is recommended for all cases. Manipulation of the spine and sciatic stretching give good results in selected cases. In chronic persistent cases of lumbosacral and sacro iliac pain, operation is advised.

Spondylolisthesis—Data presented by Meyerding do not bear out observations by others that spondylolisthesis is more common in females, about 62 per cent of the patients in his series were men. Trauma appears to be a significant factor in the etiology, although the frequency of congenital defects and the apparent instability of the lumbosacral joint are additional factors. About 38 per cent of the patients ascribed the cause to trauma. Symptoms are mainly backache, which comes on either gradually or suddenly, if suddenly, severe trauma is usually associated. The absence of symptoms with the patient at rest, and aggravation of pain on exertion, are characteristic. Patients are treated by casts, braces, corsets, or fusion of the third, fourth and fifth lumbar vertebrae and the upper part of the sacrum.

Blood Serum Calcium Healing of Fractures—The results of several hundred blood determinations made by Speed on fracture patients show that immediately after fracture the blood phosphorus is low, the blood calcium is normal, the average admission calcium-phosphorus product is within normal limits, from 36 to 40, within twenty-four hours after any major fracture the blood serum phosphorus content rises and remains high, coming down slowly, possibly varying with the period of disability from three to five weeks. Increased muscular exercise may hasten this. The blood serum calcium content remains about stationary, diet has little or no effect on either calcium or phosphorus content of the peripheral blood after any operative procedure there is an almost immediate rise in blood serum phosphorus followed by a rapid fall to normal. Experimental work done on dogs showed that in healthy dogs reduction of blood serum calcium and phosphorus or elevation of blood serum calcium and reduction of phosphorus have no consistently demonstrable effect on the healing of experimental fracture even after a considerable period of time or with a reduction which gives a numerical product of less than 30 amounts of each per hundred cubic centimeters of blood serum being taken. After thyroparathyroidectomy, however, with resulting lowering of blood serum calcium and raising of blood serum phosphorus even when the product does not get anywhere near as low as 30 there is great delay in bony union after experimental fracture in dogs. Taking average human beings suffering fracture it

seems then impossible to prognosticate delayed union or non union after fracture by any estimation of blood serum phosphorus calcium content or their numerical product.

Influence of Alterations in Circulation on Repair of Bone—Perrse and Morton have shown previously that blocking the deep veins to produce venous stasis at the site of healing results in an increased callus formation and accelerated bone repair. This is a useful procedure in treating delayed union of fractures. Obstruction of the lesser saphenous vein has no influence on the healing of the fibula. Blocking the arterial circulation by ligation of the main trunk has no effect because of the rapid development of collateral circulation. When the main artery and its branches are removed there is delay in bone repair, but healing eventually takes place. Removal of the lumbar sympathetic trunk and ganglions makes little change in the process of bone repair in the extremity.

Scoliosis Treated by the Fusion Operation—Study of the end results in 360 cases leads Hibbs et al. to the conclusion that spine fusion is indicated in the treatment of scoliosis (a) to prevent increase of deformity in the progressing scoliotic, (b) to maintain a previously gained correction, (c) to relieve pain in a progressive lateral curvature. To accomplish this, constant support of the correction should be applied for from six to twelve months after operation. In order not to lose preoperative correction, the operation is performed through a posterior fenestration of the corrective cast. The area of fusion should be correctly selected identified at operation, and adequate in length. The best form of correction of lateral curvature in their hands is a combination of head and pelvic traction with complete lateral bend. This is accomplished by the use of an anteroposterior hinge turnbuckle jacket. The increase of lateral curvature is closely associated with the skeletal of the spine.

Peg Leg Cast—The peg leg cast is recommended by Blount for the ambulatory management of many hip abnormalities in children. It is desirable when simple fixation in abduction is sought, and it has been used to advantage postoperatively. In the treatment of chronic hip infections with shortening and vicious adduction, it is the method of choice for the correction of position and immobilization of the hip. It is specifically indicated during the active stages of coxa plana and coxa vara.

Supination Sign—Yeigerson states that if the elbow is flexed to 90 degrees, the forearm being pronated, and the examining surgeon holds the patient's wrist so as to resist supination and then directs that active supination be made against his resistance, pain definitely localized in the bicipital groove indicates a condition of wear and tear of the long head of the biceps, or synovitis of its tendon sheath. The sign will be found negative in cases of partial or complete rupture of the supraspinatus tendon. This sign has been found useful in cases of shoulder injury.

 Jr. Bahia Brazil—p. 65

Complement Fixation Tests with Yellow Fever Antigens—The complement fixation test for yellow fever as performed by Frohisher has given about 87 per cent correct reactions with serum from 159 human beings and 175 monkeys. It is believed that, in view of difficulties in clinical interpretation and the natural immunity of monkeys, the figures expressing the accuracy of the test should actually be about 90 per cent. The complement fixation tests in which yellow fever antigens are used appear to be highly specific for yellow fever. There is no good evidence of undue interference with the test by other diseases nor does there seem to be any good reason for such interference. However, it is possible that the presence of certain diseases, especially syphilis, may sometimes cause falsely positive reactions. Complement-fixing bodies appear to reach a maximum concentration in the blood of monkeys after the lapse

of from thirty to forty days. They seem to remain in the blood stream for periods varying from a few months to more than a year. In tests of monkeys for immunity to yellow fever it is believed that more reliable results will be obtained if the serum is not drawn until after thirty days following infection. The same probably is true also of human beings. Experiments have confirmed the observation of Davis that previously actively immunized monkeys in which the titer of complement-fixing bodies has declined to a vanishing point because of age will respond to second injections of virus with a production of complement-fixing bodies in the absence of fever. It is suggested that this may indicate one of three possibilities: (1) an obscure second infection which does not manifest itself clinically, (2) an allergic reaction, (3) the development of complement-fixing bodies as a result of the presence of the virus as a foreign protein, in which case the complement-fixing bodies might be distinct from the protective bodies.

- *Incidence of Influenza Among Persons of Different Economic Status During Epidemic of 1918 E Sydenstricker—p 154

Influenza Among Persons of Different Economic Status During Epidemic of 1918—Sydenstricker states that perhaps no observation during the great influenza epidemic of 1918-1919 was more common than the familiar comment that 'the flu hit the rich and the poor alike.' Apparently there was ample ground for a belief in the impartiality of the disease. Its widespread prevalence throughout the country, the frequency with which households in every social class were attacked, and the fact that prominent persons in every community were struck down, were among the outstanding, undeniable experiences in the epidemic. A certain consolation seemed to be afforded by the thought that the pestilence was democratic, even in so dreadful a sense, in its behavior. Like many conclusions based on general impressions, this observation was true only in part. Epidemic influenza undoubtedly was prevalent among all classes of persons and its mortality toll was levied from the wealthy as well as from the poor. But when the generalization was subjected to the closer analysis afforded by actual records of influenza incidence in 1918 in enumerated populations, the interesting indication appeared that there were marked and consistent differences in its incidence—with respect both to morbidity and to mortality—among persons of different economic status. An association between the incidence of epidemic influenza and economic condition was manifested. Apparently the lower the economic level the higher was the attack rate. This relationship was found to persist even after allowance had been made for the influence of the factors of color, sex and age and certain other conditions.

Infections with Yellow Fever in England—Three cases of direct infection with a Brazilian strain of yellow fever are recorded in laboratory workers in London by Low and Fairley. Two of the patients never came into contact either directly or indirectly, with infected monkeys, they acquired the disease during routine hospital examinations: one in making blood slides and performing a white cell count, the other in doing routine biochemistry on a specimen of blood sent to the laboratory. The incubation period in both cases was ten days. Monkey inoculation showed that the blood of one patient was infective for at least eighty-nine and one-fourth hours after the onset of fever, despite the earlier injection of immune convalescent serum. The hitherto little appreciated danger of routine blood examination in cases of yellow fever during the first four days' illness, and probably also in the incubation period, is emphasized. It is strongly urged that in endemic areas when yellow fever is prevalent gloves should invariably be worn when taking blood, whether or not the case is suspected of being yellow fever.

Malignant Disease of Lung—Edwards states that the onset of malignant disease of the lung is generally gradual and insidious but sometimes is initiated by a pyrexial attack commonly labeled influenza. For months, the history in others may disclose nothing except increasing lassitude without localizing symptoms. This symptom is later accompanied by dyspnea or nonproductive cough, both tending to become worse. The general appearance is often good and weight may even be gained at this period. Hemoptysis occasionally occurs early. Irregular pyrexia may be an early symptom but the temperature is rarely high until the later stages when there is retention of secretions, or when necrosis has occurred in the center of the growth. A sudden attack of hemoptysis, associated with the expectoration of a quantity of purulent sputum, occurs occasionally in malignant disease and tends to confuse the condition with pulmonary abscess especially as it is often preceded by a rise and succeeded by a fall of temperature. Pain is rare in the early stages but until the pleura or mediastinum is involved is never severe. Dysphagia occasionally results from the pressure of secondary deposits in mediastinal lymph nodes on the esophagus and hoarseness from pressure on, or involvement of the left recurrent laryngeal nerve. The signs vary according to the type of the disease. In the bronchial growths the physical signs are those of pulmonary atelectasis, bronchial breathing of a blowing type, some dullness and often increase of voice sounds when the obstruction is incomplete, with dullness and weakness or absence of breath and voice sounds when complete bronchial obstruction is present. In the central or alveolar type, physical signs may be absent or may consist of localized dullness associated with weakness of breath and voice sounds. Extrapulmonary signs should also be sought for, such as enlarged supraclavicular lymph nodes and paralysis of the homolateral diaphragm due to involvement of the phrenic nerve. Evidence of venous obstruction, such as dilatation of the superficial veins of the chest and the veins of the upper limb and neck is comparatively rare in pulmonary neoplasms. Effusions of the pleura are usually late and are often hemorrhagic. Bronchiectasis secondary to the obstruction results in a proportion of cases and its symptoms may mask those of the initial lesion. The fact that the signs are atypical of any of the common lung diseases should immediately suggest the possibility of malignant disease of the lung. Diagnosis may be confirmed by further investigations. These comprise roentgen examination before and after pneumothorax and the introduction of iodized poppy seed oil into the bronchi, bronchoscopy, thoracoscopy and finally, exploration of the thoracic cavity. In the past when a diagnosis of malignant disease has been established the tendency has been to abandon all

hope As diagnosis is becoming possible at an earlier stage, some definite efforts should be made to deal with the problem of malignant disease of the lung in a more active way than by palliation of symptoms alone

Hydatid Disease in England—According to Brailsford, hydatid disease which is not rare in England and which has a high mortality rate could be eradicated by the burning of all hydatid cysts and the isolation of infected dogs until all adult parasites have been expelled and destroyed This could be accomplished by (a) Education of the public particularly butchers and farmers, by suitably illustrated leaflets and posters for slaughterhouse premises (b) Strict enforcement of the by laws prohibiting dogs in slaughterhouse premises (c) Compulsory notification of all cases of hydatid cysts and the destruction of the cysts by the sanitary authorities (d) The inspection of farms on which the infested animals were reared and isolation treatment of all suspicious dogs

Meincke Clarification Reaction—Prentice advocates simplification of the Meincke clarification reaction by eliminating three of the tubes containing serum (A, B and C) and using only tube D Its micromodification is rapid in operation, gives a high percentage of agreement with the Wassermann reaction, is very sensitive and is easy both to perform and to read As a routine test for syphilis in the patients in a mental hospital, it offers advantages over any other test It has proved reliable

Ovarian Transplantation—Allowing that surgical technique may develop to such an extent that the blood supply and drainage can be assured by the anastomosis of the vessels of the transplanted ovary to the vessels of the bed in which the transplant rests, Hannan does not believe that there is any hope of being able to deal effectively with the lymphatic supply and drainage With regard to the nerve supply, even if it were possible to anastomose the nerve supply of the transplant to the nerve supply of the bed, regeneration of the anastomosed nerves would take place only a considerable time after trophic changes had occurred in the transplant He therefore considers that the transplantation of a compound gland, such as the ovary, is of no value, since its physiologic activity cannot be maintained Moreover, a consideration of the anatomy and physiology of a compound gland such as the ovary, and of modern surgical research on compound glands in general, affords no prospect of successful ovarian transplantation in the future

Indian Journal of Medical Research, Calcutta

18 1436 (Dec) 1930

*Parasitology of Malaria R Knowles R S White and B M Das Gupta—p 1

Parasitology of Malaria—According to Knowles et al the distribution of malaria in general throughout the world is limited by the summer mean isotherms of 60 F The distribution of *Plasmodium falciparum* throughout the world is limited by the summer mean isotherms of 70 F It is shown that in Australia the malaria parasites appear to have only recently gained a footing and to retain still their northern hemisphere rhythm They may be expected to extend their distribution over this continent unless artificially checked The distribution of *Plasmodium malariae* throughout the world suggests that this is a dying species with existing foci at the Burma-Yunnan frontier, the relics of Gondwanaland, and the Caucasus The relative proportion of the three species within the area bounded by the 70 F summer isotherm should theoretically be *Plasmodium vivax* 39 per cent, *P. malariae* 18 per cent and *P. falciparum* 43 per cent The actual proportions were quite different, being *P. vivax* 43 per cent, *P. malariae* 8 per cent, and *P. falciparum* 49 per cent From this it is concluded that the factors governing the relative distribution of the three species are not yet at all understood Mixed infections constitute about 37 per cent of the general malaria of the world and are distributed as follows *P. vivax* plus *P. malariae* 9 per cent, *P. vivax* plus *P. falciparum* 79 per cent *P. malariae* plus *P. falciparum* 10 per cent *P. vivax* plus *P. malariae* plus *P. falciparum* 2 per cent The relative gametocyte output of the three species is for *P. vivax* 21 per cent, *P. malariae* 45 per cent and *P. falciparum* 19 per cent Great variations are found especially in the case of *P. falciparum* The conclusion of Sinton that the maximum output of gametocytes by *P. falciparum*

occurs after the close of the transmission season is confirmed A preliminary study of untreated cases of malaria by enumerative and cultural methods leads to the belief that usually malignant tertian malaria does not persist in an individual in the absence of repeated fresh injections of sporozoites The development of crescents is not associated (in culture) with an increase in the acidity of the environment Growth and development of both schizonts and gametocytes of all three species in culture is inhibited below a pH of 6.0 Given a competent observer, examination of 100 fields of a thin film plus a reasonably careful examination of one thick film will enable a positive diagnosis to be made in 95 per cent of all cases of developed malaria but will discover only 67 per cent of the cases of mixed infection However highly trained the observer, the authors' experiments show that it is utterly impossible to make a species diagnosis from the examination of a single ring trophozoite form They also show that a 95 per cent agreement in diagnosis can be expected from five minutes' examination of a thin film by recognized experts From this it is inferred that the data used can generally be accepted as representing the actual facts as at present known with regard to the distribution of malaria species throughout the world

Gelatinothorax—Because of unsatisfactory results obtained with intrapleural injections of oil, Hunter sought for a substitute that would possess compressive and antiseptic properties A medium was prepared the basis of which is gelatin with acriflavine hydrochloride as the antiseptic The fundamental principle is that the gelatin solution must not solidify in the cavity when injected, and this principle is observed by the percentage of gelatin employed and by superheating so that the solidification properties of the medium may be impaired if not entirely, to a degree It was found that a 5 per cent gelatin solution met requirements, and this was tested by incubating at 30 C for forty eight hours the solution remaining liquid at this temperature giving a margin of at least 7 degrees centigrade This gelatin is not the nutrient gelatin employed for the growth of bacteria, but ordinary sheet gelatin dissolved in physiologic solution of sodium chloride The dilution of acriflavine employed is 1:2,000, and the preparation is adjusted to pH 8.0 This medium keeps indefinitely Solidification never occurs over 30 C It is usually solid before using, and is heated and liquefied in a water bath to a temperature of approximately 45 C The medium should be slightly above blood heat when withdrawn (by syringe) from the bottle When cool, phosphates may appear as a sediment in the bottle but they disappear on heating It would be unwise to attempt to clear this medium with egg albumin as performed in the preparation of nutrient gelatin for bacteriologic purposes This gelatin acriflavine preparation was tested for its action on a pyogenic organism as follows Five cubic centimeters of a heavy culture of *Staphylococcus aureus* emulsified in sterile physiologic solution of sodium chloride was added to 30 cc of gelatin acriflavine After inoculation the flask was incubated for twelve hours No growth was obtained on subsequent subculture showing that the gelatin acriflavine mixture was not only inhibitory but lethal to a virulent pyogenic organism recently isolated from the tissues By

the incubation at body heat and at lower temperature it was found that the gelatin remained quite liquid and was easily drawn through a fine needle, and the antiseptic action of the acriflavine was bactericidal on short exposure. Further tests showed that this preparation was bactericidal to tubercle bacilli, the test was as follows. Two specimens of sputum, highly infected with tubercle bacilli (three plus), were pooled, subjected to the action of a strongly alkaline solution of sodium hypochlorite, and carefully washed. One half of the resultant sediment was emulsified in 5 cc of sterile physiologic solution of sodium chloride, from which 1 cc was extracted and injected subcutaneously into a guinea pig (positive control). The remainder of the sediment was emulsified in 5 cc of a 5 per cent gelatin solution in acriflavine (1:2,000) and incubated for twenty-four hours. A guinea pig was then injected also subcutaneously with 1 cc of this emulsion. After seventy-two hours' exposure at body heat, another animal was so treated. The positive control developed a lesion at the site of inoculation, and smears therefrom showed abundant pus cells and a few tubercle bacilli. At necropsy, the spleen showed a generalized tuberculosis. The incubation period was six weeks. The other two guinea pigs showed no lesions after three months and were killed. At necropsy no lesions were found. It was observed therefore, that (1) the use of gelatin does not impair the efficiency of the antiseptic employed and does not provide a nidus for growth; (2) this preparation will be of the utmost value in disinfecting the cavity. Ten patients have been treated with gelatin acriflavine and some of them responded after all other treatments had failed.

Bacillus Calmette Guérin Strain of Tubercle Bacillus

Sasno and Medlar present experimental data that leave no doubt that it is possible to enhance greatly the virulence of BCG if the culture is grown in a suitable environment. To determine the proper environment was not an easy matter, and to get the original culture to grow luxuriantly in the new environment was also difficult. It is essential to have the pH adjusted between 7.2 and 7.4. This has necessitated the titration of Sauton's medium just prior to the addition of the fresh rabbit serum and to the transfer of the culture, for the medium is rather unstable. Fresh unheated rabbit serum seemed to be essential for a rapid increase of virulence. The factors that determine the virulence of pathogenic bacteria are but little understood. This is especially true for the tubercle bacillus. Environment plays an important part, but the factors necessary to produce the proper environment are largely unknown. From their study the authors believe that the pH of the medium is one important factor and that there are substances present in unheated normal serum which greatly assist the tubercle bacillus to regain its pathogenicity. BCG, when grown under such an environment, developed a virulence which was greater than that of any other culture of tubercle bacillus which the authors have had in their laboratory. For more than six months, since the return of virulence they have kept this altered BCG culture on Petroff's egg medium. It is still virulent, but to a lesser degree. Another fact of importance is that with the return of virulence the organism is equally pathogenic for guinea-pigs, calves and rabbits. It would seem that the normal rabbit serum has made available substances which have made the culture equally virulent for various animals. The work substantiates the observations of Petroff and Branch on the 'dissociation' of BCG. They have not used the same method, but their end results are similar. The gross appearance of virulent and of nonvirulent cultures is different. The virulent culture is smooth, veil like, colorless, and easily emulsified. The culture of low virulence is rough, compact often chromogenic and emulsified with difficulty. In their work the authors have purposely taken the original culture without any attempt at dissociation. There can be no question of contamination. It was possible to alter the original BCG culture in its gross appearance and in its virulence without resorting to isolation of single colonies. Since it is possible to bring about such a marked alteration of BCG "in vitro" and since so little is known relative to the factors that enhance or retard the pathogenicity of the tubercle bacillus, it would seem essential to use great caution in any application of BCG as a prophylactic vaccine against tuberculosis. Great care must be used in the selection of the culture medium for cultivation of BCG if it is to be used as a prophylactic

vaccine. The pathogenicity of BCG varies greatly with the environment. While Calmette's observations point, so far, to the innocuousness of the vaccine, still all control over the tubercle bacillus and its actions is gone once it gains access to the tissues. BCG is not a "virus fixe" unless it is kept in a certain environment.

Two Methods of Operation in Inguinal Hernia.—Bonneru discusses two new methods of operative technique for use in cases of inguinal hernia. The first method proposed by Bossy, is as follows. After the hernial sac has been detached but not opened, its free end is grasped with long curved forceps without teeth and is thrust back into the abdomen by invagination. As the forceps are brought upward and outward, their end is pressed against and through the inner surface of the abdominal wall at a point as close as possible to the spina iliaca anterior, until the soft parts are passed. On the projection thus formed a short incision is made so that the extremity of the forceps, with the sac, may be brought through the wall. The sac is then grasped and fixed to the surface of the aponeurosis or even to the skin. The forceps are drawn out. The author does not think favorably of this method, especially of the modified technique to be used in long standing adherent hernias which involves separating the fibrous tissues common with the testis and invaginating the whole into the abdomen. If this were done and an orchitis should develop later the testis would be in an extremely unfavorable position. In fact, the only conditions in which the author considers reduction *en masse* expedient are cases of ptosis of the large intestine, and even then he advocates preliminary opening of the sac to verify its contents. The second method, proposed and used extensively by Lembo, consists essentially in finding separating and using the internal and external cremaster muscles as material for reconstruction of the wall. The author considers this method much more consistent and practicable than the first one.

Primary Pneumococcal Peritonitis. Two Cases.—Darre et al. report two cases of pneumococcal peritonitis in adults which they consider significant because of the fact that the disease is rarely observed except in children. The two patients presented an almost identical syndrome: brutal onset of diffuse abdominal pain resembling colic, nausea, alimentary then bilious vomiting, profuse bilious and fetid diarrhea, drawn necks, high fever and rapid pulse. The differential diagnosis between pneumococcal and appendicular peritonitis is easy since the presence of diarrhea and the almost complete absence of abdominal contraction are pathognomonic of the pneumococcal form. However, in the two cases reported the usual difficulty was experienced in deciding between pneumococcal peritonitis and alimentary intoxication. In fact in both cases the first diagnosis

made was that of alimentary intoxication, probably partly because of the definite elimination of the ordinary forms of peritonitis and because the pneumococcal form is so seldom encountered in adults. The correct diagnosis was based on the fact that the intensity and rapidity of the alteration in the patient's general condition did not seem consistent with the usual symptoms of alimentary intoxication; the abdomen proved not to be absolutely supple but instead presented a slight resistance in the subumbilical area and the iliac fossa; the porraceous appearance of the vomit; the development of herpes of the lips and an excess of polymorphonuclears in the blood also seemed to indicate peritonitis. In one case surgical intervention was not attempted, and the patient died. The second patient was operated on after five days with excellent results. The authors hesitate to recommend any particular method of treatment since the observation of two cases does not seem sufficient basis for assuming that the method of delayed operation usually prescribed for children, is the treatment of choice for adults.

Acute Nephritis from Ingestion of Corrosive Mercuric Chloride. R. Chosy and E. Perrot—p 1789

Azotemia in Typhoid—Brule and Lenegre report two cases of azotemia in typhoid patients who had received injections of acriflavine hydrochloride. They also report a case in which azotemia was observed in a typhoid patient who had not been given the acriflavine hydrochloride treatment; the azotemia was not accompanied, moreover, by either albuminuria or cylindruria and marked diuresis was present. Since it has been proved experimentally that acriflavine hydrochloride sometimes causes azotemic nephritis, and since azotemia may also be caused by the typhoid itself, diagnosis becomes a delicate problem in cases in which azotemia is observed after injections of the medication and the urea content of the blood has not been determined before the beginning of the treatment. Moreover, the two causes acting simultaneously in the same patient, could have a cumulative effect. The authors do not consider these facts sufficient grounds for discontinuing the use of acriflavine hydrochloride in the treatment of typhoid patients, however, since it has been employed in so many instances with excellent results. They merely advise careful observation of the patient and regular determination of the urea content of the blood, even in the absence of pathognomonic urinary symptoms.

Pulmonary Tuberculosis in Diabetic Patients—Labbe et al report two cases that they have observed for three years and one that they have observed for four years in which tuberculosis developed in the course of diabetes and in which insulin treatment combined with the establishment of a therapeutic pneumothorax has given good results. In the last case the patient was in a condition of diabetic coma at three different times and three times presented acute pulmonary symptoms. Yet with careful attention to diet and regular doses of insulin and with a pneumothorax on the left side and a phrenicectomy on the left, she was able to lead a comparatively normal life at the time of writing. While there can be no hope of an actual cure in such cases, the authors point out the possibility of enabling patients to control their condition by a combined treatment of the diabetes and tuberculosis so that they may live in apparent good health for an indefinite period.

Local Anesthesia in Major Operations on Stomach—Judine reports a number of long and complicated operations

—resections for peptic ulcers after gastro-enterostomy, sub-total resections for precardiac gastritis ulcers, total and sub-total gastrectomies for cancer and other diseases—in all of which used local anesthesia. He attributes the excellent results to the secured to the method of anesthesia. Patients already dangerously weakened cannot be kept under the influence of a profound general narcosis for two or three hours without having intestinal disturbances that interfere with the completion of the operation. A less profound narcosis does not insure sufficient relaxation of the abdominal wall and thus make difficult to gain access to all parts of the abdominal cavity. An incomplete narcosis, moreover, is dangerous in its effects, for an insufficiently paralyzed nervous system is easily overexcited and may lead to operative shock. The use of local anesthesia, however, makes it possible to avoid these difficulties. There is no general intoxication and a complete relaxation of the abdominal wall is secured. The only wholly effective method of preventing irritation of the central nervous system is by complete blockage of the afferent nerves.

- Roffo's Neutral Red Reaction in Diagnosis of Cancer. J. Bottin—p 765
Rectal Necrosis with Avertin. P. Guns—p 765
Preventive Vaccination of Adult Guinea Pigs with BCG by Ocular Method. P. Nels—p 774

Roffo's Neutral Red Reaction in Diagnosis of Cancer—Bottin first reviews the literature in which numerous authors give the results of experiments to determine the value of Roffo's neutral red reaction in the diagnosis of cancer. The totality of the observations reported showed that among 1,211 cases of cancer a positive reaction was obtained in 70.5 per cent and among 3,807 cases of noncancerous conditions a positive reaction was obtained in 13.4 per cent by the use of the neutral red test. The author's personal experiments include 140 cases of cancer in 89 of which (63.57 per cent) the reaction was positive and in 50 of which (35.71 per cent) it was negative. Among 140 cases of noncancerous conditions, he obtained 45 positive reactions (32.14 per cent) and 89 negative reactions (63.57 per cent). Since the positive reactions in noncancerous conditions included a great variety of diseases, some of them difficult to distinguish from cancer in the early stages, the author feels that Roffo's reaction has little if any practical diagnostic value. He continued his experiments, however, in order to ascertain whether the reaction could throw any light on the disturbances produced in the organism by cancer or on the general disorders that tend to produce cancerization. He found that it is evidently favored by a high carbon dioxide content of the blood, that it seems due to a disequilibrium that is capable of passing through inflamed membranes and that the reaction is found most often and to the greatest degree in markedly cachectic conditions, whether or not the cachexia is connected directly with cancer.

Vaccination in Persons Who Had Had Mild Smallpox and in Patients with Chickenpox—Among forty-five persons who from eight to nine years previously had had an attack of modified smallpox (varioid), Diem observed not a single entirely successful vaccination. In about 10 per cent of the cases the effect of vaccination was slight and could be estimated at from one fifth to one third of a complete success. These results are surprising, since in other localities vaccinations have been successful after much shorter periods. From the point of view of immunology this epidemic of modified smallpox is more like true smallpox than are other forms of smallpox, especially that form which is designated as alastrim. The author also investigated the effects of vaccination in patients with chickenpox.

Some patients were vaccinated before the exanthem became manifest, others while the eruption was most severe, and a third group during the period when the eruption was disappearing. In all of these cases the vaccination results were positive. In comparing the effects of the vaccination in patients with chickenpox with those in healthy children, differences could not be detected.

- *Primary Intra Ossal Chronic Abscess (Brodie's Abscess) I Radice—p 1258
- Calcium Content of Bone Fragments at Site of Experimental Fractures C Loreto—p 1283

Primary Malignant Tumors of Lung—Gioja deals with a case that came under his observation and presents a number of views on the diagnosis, prognosis and treatment of primary malignant neoplasms of the lung, calling attention above all to the frequency with which these tumors are confused, from the roentgen point of view, with hydatid cysts of the lung, and to the difficulties that still prevent an early diagnosis. From the surgical point of view the possibilities of radical treatment are found in only a limited number of cases, owing to the difficulties encountered in endeavoring to reach an early diagnosis. Some operators report considerable improvement from the use of local anesthesia. Alessandri, followed by almost all operators of late, establishes a pneumothorax the day before the operation, and finds this refinement in the technic of considerable importance.

Primary Chronic Bone Abscess (Brodie's Abscess)—Radice states that Brodie's abscess is more common than is supposed, being found, according to some statistics, in from 7 to 12 per cent of the cases of osteomyelitis. He describes four cases that came under his observation. On the basis of his observations and the reports in the literature, he endeavors to give a complete clinical picture of this interesting disorder and to establish within precise limits its pathogenic bases.

- *Resection of Lumbar Sympathicus Thermometry M Ronzini—p 620
- Strumitis Due to Pneumococcus L Docimo—p 627

Research on Disturbances Associated with Spinal Anesthesia—Biancalana points out that the variability in the physiologic conditions of the spinal fluid, together with the diversity of technic employed in spinal anesthesia complicates research on the pathogenesis of the disturbances resulting from rachianesthesia. The results of clinical and experimental research on the phenomenon of the solution of the substances injected into the spinal canal and on the neurotropism are contrary to the hypothesis of the movement of the anesthetic to the bulbar centers, since spinal anesthesia is applied to the lumbar spaces and none of the maneuvers calculated to favor the diffusion of the anesthetic upward is employed, and since the patient is kept after the puncture, in a horizontal or upright position. The possibility of doses of an anesthetic attaining the superior nerve centers may be realized when the technic employed is different or when the puncture is applied to the thoracic spaces. The Trendelenburg position applied for a moment after rachianesthesia is useful in all disturbances possibly due to bulbar anemia.

Resection of Lumbar Sympathicus Thermometry—Ronzini, following researches reported in a previous article from which it became evident that lumbar sympathectomy does not induce immediate vasoparalysis in the adjoining femoral artery, in this article studies the effects immediate and remote of lumbar sympathectomy on the temperature of the lower limb. He experimented on the dog using a sensitive thermo-electric needle, which was implanted in the muscles of the hip. In some

of the individuals there developed transitory hyperemia and hyperthermia but in most of the dogs positive thermometric reactions were lacking. The possibility of correcting the trophism of a limb affected by disturbances of angiospastic origin thus remains doubtful. But since the good results secured by other authors by such operations on man in angiospastic diseases of the extremities cannot be categorically denied on the basis of researches on animals, the author concludes that in order to explain the diversity of results in the two fields—the clinical and the experimental—it may be postulated that the lumbosacral sympathicus, assuming in pathologic conditions a state of tonic hyperexcitation, acts under the influence of an essential pathogenic factor of the angiospastic disease.

- Atypical Ventricular Forms in Cardiac Insufficiency and Angina Pectoris R Capo and G Bagnaresi—p 627

Congenital Atresia of Orifice of Pulmonary Artery—Costa describes a rare case of atresia of the orifice of the pulmonary artery in a man, aged 20. It is exceptional that life, under such conditions, was prolonged beyond childhood. In addition to the persistence of Botallo's duct, a peculiar malformation was associated with the atresia of the artery which the author refers to the superior septum, namely a cribrate condition of the anterior circumference of the foramen ovale. The author also presents a rare type of tendon cord in a child extending between Botallo's foramen and the mitral valve. This observation, which some connect with the superior septum, is referred by the author to the intermediate septum. In the case of atresia of the orifice of the pulmonary artery, the compensation was effected in great measure by the patency of the foramen ovale and the persistence of Botallo's duct. The patient presented an intense cyanosis and osteopathy of the fingers and toes. There was no focus of pulmonary tuberculosis.

Etiopathogenic Researches on Pleuritis Due to Therapeutic Pneumothorax—Scalabrino gives the results of his histologic researches on the pleura not only in persons in whom necroscopy showed no intrathoracic tuberculous lesions demonstrable microscopically, but also in tuberculous persons subjected to collapse therapy of the lung. On the basis of the results secured, he considers that, in the majority of subjects without tuberculous lesions microscopically visible there are found, at the microscopic examination in the parietal and the visceral pleura especially at the site of scars due to thickening remnants of a tuberculous process probably due to an invasion from a primary focus. On the basis of these data he assumes that there occurred during the pneumothorax treatment a reactivation of these foci that had long been dormant. The clinical manifestations of this reactivation may be profoundly different in different cases, in relation chiefly to the histologic type that the inflammation in the pleura may assume (ranging from simple hyperemia to the exudative vascular type), and only secondarily in relation to the general and local allergic factors.

12 1019 1112 (Dec.) 1930 Partial Index

- *Etiology of Aphthous Stomatitis V Zamorani—p 1095

Etiology of Aphthous Stomatitis—Experimental researches lead Zamorani to believe that aphthous stomatitis in children is caused by the virus of herpes simplex. In the mouths of six children with aphthous stomatitis, well differentiated from herpetic stomatitis the author demonstrated the presence of a virus which when inoculated into the conjunctival sac of the eyes of rabbits (through the scarified corner) caused a typical experimental herpetic keratoconjunctivitis which confers immunity to the eye both against a virus of the same nature as that which was inoculated and to the virus of herpes simplex. One rabbit developed encephalitis after the experimental lesion of

the eye. Serial direct inoculation from eyes affected with experimental keratoconjunctivitis of stomatitic origin to normal eyes of other rabbits caused the transmission of the disease, which presented an intense nature even after the sixth transfer. Bacteria cultivated from eyes of rabbits with the experimental disease are not pathogenic to the eyes of normal rabbits. The inoculation made with filtrates of tissues affected with the disease failed to cause the experimental disease, though it conferred an attenuation of the normal receptivity of the tissues to the infection. The author says that the especial features that herpetic diseases show in children are probably due to the fact that in childhood the mucosae are more receptive than the skin to the herpetic virus.

 Treatment of Menstrual Disorders. A. Schweitzer—p. 1210

Heart and Aorta in Case of Addison's Disease—Tattomi describes the orthodiagraphic records of the heart and the aorta in a case of Addison's disease and reaches the conclusion that in this disease those organs in direct relation to the pressure disequilibria undergo volumetric changes comparable to manifestations of a state of hypotonia, which invades these organs under the action of the epinephrine deficit due to suprarenal insufficiency. The aortic hypotonia reveals itself by a more or less marked dilatation of the vessel caliber, the myocardic hypotonia manifests itself by a weakening of the whole organ but especially of the left ventricle.

Acute Hemocytoblastic Syndrome—Esposito describes a new case of acute hemocytoblastic syndrome developing in a boy, aged 9, previously well, with fatal evolution in fifteen days. He gives a brief account of the clinical manifestations and the hematologic observations.

- *Symptomatology of Echinococcosis of Liver in Children. G. Vitetti—p. 1201
 Ionic Dissociation and Protein Content of Blood Serum of Infants with Nutritional Disturbances. B. Vasile—p. 1217
 *Malignant Abdominal Sarcoma with Rare Localization in Child. G. Bovenzi—p. 1227

Symptomatology of Echinococcosis of Liver in Children—Among a group of fifty-eight children, aged from 1 to 12 years, with echinococcosis of various organs, observed by Vitetti, the infection was localized in the liver in thirty-four. The condition is more frequent in children of about 12 years and it is never observed in children aged less than 3 years. The most frequent localization of hydatid cyst in the liver in children is the right lobe (eleven out of thirty-four cases), coming next in importance is that of the left and central lobes of the liver (with nine and five cases, respectively, out of thirty-four). The liver reacts against the hydatid process by increasing its size and consistency. This phenomenon of hyperplasia is more marked in children than in adults. The evolution of hydatid cyst is protracted, from one to four years in the author's cases after the discovery of the cyst, as a rule, hydatid cysts of the liver in children develop in a silent form until accidentally discovered. Owing to the fact that children are more exposed than adults to trauma, the rupture of hydatid cyst into the peritoneal cavity is more frequent in the former than in the latter. The author makes reference to the diagnostic value of several tests. The exploratory puncture that should represent the best diagnostic resource is dangerous. Though performed with the best asepsis, it may give origin to anaphylactic hemorrhagic or even suppurative phenomena. As to treatment, surgery is the only reliable method; the earlier the operation is performed the better are the results.

Malignant Abdominal Sarcoma with Rare Localization in Child—Bovenzi reports the case of an unusual form of malignant abdominal tumor diagnosed clinically as abdominal sarcoma with peritoneal localization in a child aged 6 years. The condition, which at first did not seem serious, became

aggravated by the rapid and sudden development of the tumor. A laparotomy revealed the presence of an inoperable malignant sarcoma of large size, occupying the entire abdominal cavity. It originated in the vicinity of the spinal column, to which it was united by a large pedicle which crossed the abdomen in its entire anteroposterior diameter.

 Two Rare Cases of Prolonged and Recurring Osteomyelitis. U. Fogliani—p. 1744

Meinicke Clarification Test in Relation to Wassermann Test—Sosca recalls that the Meinicke clarification test is a modification of the Meinicke flocculation test. The positive reaction consists in the clarification that is produced in the serum mixture when brought into contact with the dilute antigen. In the negative case, the serum mixture remains turbid. From the results secured in the testing of 200 serums, the author concludes that the Meinicke clarification test is plainly more sensitive than the Wassermann test and constitutes an excellent control and valuable aid to the Wassermann test. It may be used therefore, in combination with the Wassermann test or alone. Since it possesses a definite specific power and a high degree of sensitiveness it is a reliable test when used alone.

 *Point of Technic in Retrogasserian Neurotomy. D. Vallone—p. 1790

Point of Technic in Retrogasserian Neurotomy—Vallone recalls that, in the first case of retrogasserian neurotomy that he observed, he became convinced that the hemorrhage that occurs as a result of the blocking of the middle meningeal artery is a drawback in the completion of the operation, adding greatly to the difficulties, and that tamponing of the foramen rotundum whether it is done with cotton or with pieces of wood or bone does not suffice to arrest effectively the hemorrhage. It seemed therefore clear that there was need of ligating the artery, and through experimentation on cadavers he found that in order to ligate the artery readily in all cases it was necessary to have on hand a number of suture carriers of different curvature and sizes, since the position of the foramen rotundum varies in its relation to the emmentia arcuata. He prepared such needles in advance and in three operations, one performed by Professor Vaghani and two by himself it was possible to ligate the middle meningeal artery at two points and thus to reach Meckel's cavity with rapidity and safety.

Semana Médica, Buenos Aires

 Simultaneous Roentgen Examination of Cystbladder and Urinary Tract. B. Varela Fuentes and P. Rubino—p. 1530

Sugar Metabolism in Obesity—Landabure made determinations of the sugar metabolism in a group of sixty-four obese persons who did not have glycosuria. The blood sugar was determined both at fasting and after the administration of dextrose. During fasting, thirty persons had a normal sugar content of the blood (from 0.7 to 1 Gm. of sugar per thousand cubic centimeters of blood), nineteen persons had a transitional glycemia (with figures ranging between 1 and 1.3 Gm. per thousand cubic centimeters of blood) and fifteen persons had a manifest hyperglycemia (with figures above 1.3 Gm. per thousand cubic centimeters of blood). After the administration of dextrose in the first subgroup (thirty patients with normal content of sugar in the blood at fasting) the results of the test were negative in eight, strongly positive in ten, slightly positive in eight and doubtful in four. In the second subgroup (nineteen persons

with transitional hyperglycemia) the results were positive in twelve, negative in six and in one person the test was not made. In the third subgroup (fifteen persons with manifest hyperglycemia) the results of the test were positive in nine, negative in two and in the remainder either the test was not made or the results were doubtful. The results indicate that 60 per cent of obese persons who have either transitional forms of glycemia or manifest hyperglycemia react in a positive manner to the test of provoked hyperglycemia. The author considers that there is a relationship between obesity and diabetes which is proved by the predisposition that obese persons have to develop diabetes. Hence the advisability of making the determinations of the mechanism of the sugar regulation in obese persons. When the test of provoked hyperglycemia does not yield positive results in strongly suspected cases of disturbed sugar metabolism, the same test should be repeated after the function of the pancreas has been exhausted.

Smallpox Vaccination in Treatment of Whooping Cough—Schiavone vaccinated ninety four children not previously vaccinated who had whooping cough. The age of the children ranged from 3 months to 9 years, though the largest number were from 7 months to 4 years. In a large number of previously nonvaccinated children with whooping cough vaccination caused a favorable evolution of the disease. As soon as vaccination takes effect, the attacks of cough diminish both in number and in intensity and in most of the cases vomiting stops. In cases in which the intensity of paroxysmal attacks is not as yet established in a determined form, vaccination prevents them while in those cases in which the paroxysmal attacks are already established in all their characteristic intensity the influence of vaccination causes their discontinuation. Vaccination is advisable as treatment of whooping cough in nonvaccinated children in good general condition. In these children, vaccination does not cause disturbances nor complications. However, the examination of children should precede vaccination in order to exclude from the treatment those children with poor nutritional conditions and those who exhibit marked weakness or tuberculosis. The influence that revaccination may have on whooping cough has not been as yet determined, because no revaccination has been made heretofore in relation to these observations. It seems advisable to make further studies on the influence of revaccination on the condition in order to find out whether the good results obtained from vaccination could be obtained also from revaccination. The mechanism by which vaccination acts on whooping cough is still unknown. It would be explained however, by the conception that it is caused by the formation of a small fixation abscess at the level of the pustule. Seventy four cases are briefly discussed.

Dolichocolon—Dagnino's paper is divided into seven chapters. The first chapter deals with the normal colon from the anatomic and physiologic points of view, and factors related with the embryonic development of the colon and neighboring organs, the development and functioning of the colon in several periods of extra uterine life and adult age and the vascular and nervous systems of the colon are discussed in detail. In the second chapter the etiology, pathology and symptomatology of dolichocolon are discussed. The author says that dolichocolon has characteristic symptoms which make of it a clinical entity. In the third chapter (which deals with the anatomic and clinical forms that dolichocolon presents), the author considers that there are as many anatomic forms of dolichocolon as there are segments in the colon. The type of the abnormality is influenced by the segment involved since the condition may be total or partial and one or several of the segments of the colon may be affected. The condition presents several clinical forms the most common of which are those of a painful type sometimes associated with pneumatosis. In a discussion of the frequency of dolichocolon, the author states that he found 50 cases out of a total number of 1000 patients with diseases of the digestive tract. The condition is more frequent in women than in men. In the author's cases the segments most frequently affected were in order of frequency the sigmoid colon, transverse colon, ascending colon cecum and descending colon. The condition of total dolichocolon is rare. In the fourth chapter are discussed the clinical and roentgen diagnoses. For roentgen examination of the colon the author advises the oral administration of the opaque substance. He objects to the use of the opaque enema. Though it saves time to the roentgenologist, it causes exaggerations of the abnormality, giving results that are not exact. The roentgen examination after the ingestion of the opaque substance permits a correct estimation of the condition on the basis of the descent of the substance. The fifth and sixth chapters include points related to the prognosis and treatment of dolichocolon. Especial emphasis is laid on the orthopedic and physical therapy. Some advice is given on diet. The seventh chapter includes the case reports of seven cases discussed in detail and illustrated with roentgenograms of several types of dolichocolon.

Results of Radium Applications in Treatment of Ozena—Podesta and Arani consider radium therapy in ozena dangerous. The dose is not as yet definite and the application of a dose of radium larger than that which the tissues can tolerate may cause permanent deformities. Because of the atrophy caused by ozena in the tissues, the septum has been rendered thin. Besides that the nasal cartilages are highly sensitive to the action of radium. If radium therapy is given to patients with ozena, the septal cartilage should be protected with proper filters. The same dose that may be only stimulative and beneficial to some of the tissues may cause extensive necrosis and large perforations in the septum either as immediate or as late results. The authors report the case of a woman aged 22 with ozena of neither syphilitic nor tuberculous origin. While receiving the treatment the patient developed regional symptoms which compelled discontinuation of the treatment after she had received a total number of six applications of radium of seven hours each once a week. The bad odor of the nose disappeared in this case though the crusts persisted. The examination of the patient showed besides a condition of atrophic rhinitis of an ozenous origin the presence of a large perforation of the septum which did not exist before the applications of radium and which proved to be caused by radium therapy. Though the literature contains few case reports of this kind the authors were able to find similar bad results reported from radium therapy in ozena such as the creation of permanent fistulas in the nose or large perforations in the hard palate. They consider it advisable to publish reports of patients who received treatment a long time ago in order to set the right value on the results of the treatment.

Fracture of Anterior Wall of Right Frontal Sinus—De Cerqueira Falcão's patient was accidentally injured by the elbow of a laborer while the latter was carrying a heavy load on his head and holding it with his hands. The blow made the patient fall down and when he got up he felt dizzy. Half an hour after the accident the patient began spitting blood and palpebral edema appeared. On palpation a hot spot was felt on

the supraciliary region where the blow had been received and slight crepitation was heard. Roentgen examination showed the presence of a fracture of the anterior wall of the right frontal sinus. Four days after the trauma had been received and when the patient had been given only a slight disinfectant and medical treatment the edema disappeared and the patient abandoned all treatment. The author says that the fractures of the anterior wall of the frontal sinus are rare and depend on several factors such as the size of the sinus, the thinness of the anterior wall and the shape of the forehead factors which could be noted in the roentgenograms of the author's patient. The blow with the elbow of another person had not been previously reported as a cause of these fractures.

Blackwater Fever Treatment.—Ujlaki believes that the hemolysis in blackwater fever is produced chiefly by the action of products of liver metabolism that have a hemolytic action on the constitutionally inferior erythrocytes. Therefore in the treatment of this condition his main object is to prevent the development of the hemolytic products of liver metabolism. He gives large doses of dextrose by mouth and in drop enemas and supports the functioning of the liver by injections of insulin. During the first three or four days the diet consists exclusively of carbohydrates in the form of bananas and sweetened fruit juices. In order to stimulate diuresis the patients are given large quantities of fluids. Even at night they receive a drop enema consisting of a 5 per cent dextrose solution containing 1 per cent of sodium bicarbonate and 40 or 50 drops of solution of epinephrine hydrochloride per liter. As a beverage they receive sweet lemonade to increase the alkalinity of the blood and thereby counteract the hemolysis. Diuretics are never used. With this form of treatment, jaundice appears only rarely and when it does it is minimal. In five cases a striking cessation of the hemoglobinemia was noted following three or four subcutaneous injections of 1 cc of autoserum. Quinine is given only in the cases in which malarial parasites are present in the blood. Even in large doses it does not produce deleterious effects if its administration is not begun until the fourth day of the supportive treatment of the liver.

Protozoal Disease of Intestine in Children.—Odriolsola states that protozoal infection of the intestine of children causes a chronic toxemia accompanied by protean symptoms. The symptoms may be divided into various groups which represent clinical forms. It is the belief of the author that protozoal infection of the intestine may be the direct or indirect etiologic factor in many intestinal disorders in children that are now considered to be the result of a faulty diet.

Leprosy Biochemical Characteristics.—Rajewski studied the biochemical characteristics of leprosy in three persons with mixed leprosy, three with nodular leprosy, two with macular leprosy and three in the exacerbation stage of leprosy (leproid erysipeloid and exacerbations with fever and nodule formation). It was found that in leprosy the carbohydrate metabolism is diminished. In this disturbance an important part is played by a dysfunctioning of the liver. Determinations of the sugar content of the blood following the intravenous injection of dextrose revealed a disturbance in the carbohydrate metabolism in all forms of leprosy.

Rational Calcium Therapy During Childhood.—Langstein points out that calcium preparations are used with good results in many disturbances during childhood, in tuberculous processes, in nervous disturbances in rickets and in allergic diseases. However, calcium therapy has the disadvantage that the effective preparations have an unpleasant taste. In calcium malonate the author discovered a preparation which has the advantage of being tasteless. In order to determine the therapeutic value of calcium malonate, its influence on the calcium content of the blood was investigated, because only those calcium preparations have a therapeutic value which effect an increase in the calcium content of the blood. The tests revealed that calcium malonate increases the calcium content of the blood considerably and because it has not an offensive taste it can be administered in large quantities. The author's experiences with calcium malonate extend over a period of six years. The preparation proved helpful in spasmodic diathesis, in the treatment of children with tuberculosis, in nervous disorders in older children in allergic disturbances and especially in tetany. In developmental disturbances of unknown etiology, calcium malonate may be added to the food. Frequently this proves helpful. In regard to the dosage it is stated that, in clonic manifestations in infants aged 1 year, from 5 to 8 Gm should be given daily. In older children, from 10 to 15 Gm is the daily dose. The preparation can be mixed with the food. In the treatment of tuberculosis, in chronic, nervous disorders or in developmental disturbances a daily dose of from 3 to 5 Gm is sufficient.

Treatment of Malignant Tumors with Radioactive Bismuth (Radium E).—Kahn states that chemical analysis of tumors and organs which had been treated with heavy metal revealed that bismuth is the only heavy metal that deposits selectively in the tumor cells. Because of this the therapeutic doses of most heavy metals are almost toxic doses whereas in the case of bismuth therapeutic effects can be obtained with doses that do not cause toxic effects. In animal experiment as well as in human beings, injections of bismuth influence the growth of tumors. However the results were only temporary, even when the injections were combined with irradiations. Experiments which the author performed in collaboration with Meizer were based on the theory that, instead of effecting a secondary radiation in the cells by irradiation from the outside it would perhaps be more effective to substitute for the irradiation from the outside a radiation within the tumor cells. It was found that the bismuth isotope radium E is the only radioactive substance which, in parenteral administration, influences the tumor cells without injuring other cells. Experiments on animals revealed a selective deposition of the bismuth preparations containing radium E, in the tumor cells. They contained eighteen times as much as other cells. The radioactive bismuth is eliminated mainly by the kidneys. Only small quantities are eliminated by way of the liver and the intestine. In these eliminating organs the bismuth is therefore often temporarily increased. However, the bismuth isotope radium E has not, like other radioactive substances, as for instance the thorium isotopes, an affinity for the reticulo endothelial system and the spleen. In the cancer patients in whom the bismuth radium E was employed the general condition improved considerably and marked changes in the tumor could be noted after several injections. However, because the technique still needs to be perfected and because of the short time of observation conclusive statements in regard to the therapeutic value of this method cannot be made as yet. The author recommends the further investigation of the method.

Chronic Tonsillitis and Its Sequelae.—Bruns asserts that it is not always simple for the internist to determine the role of chronic tonsillitis in the pathogenesis and in the course of internal diseases. The majority of internists agree that rheu-

matic diseases such as rheumatic polyarthritis, chorea, infectious heart diseases and also nephritis and the so called infectious forms of arthritis may be considered as sequelae of tonsillar foci. The author further discusses the clinical signs of chronic tonsillitis and its relation to disturbances of internal organs. He comes to the conclusion that the serious, life endangering diseases are rarely sequelae of chronic tonsillitis. However, the chronic, inflammatory foci in the tonsils frequently cause a predisposition to diseases. In regard to the indications for tonsillectomy most internists agree, in that they do not advocate the removal of the tonsils merely on the diagnosis of chronic tonsillitis. They think that tonsillectomy should be done only following a careful examination and in those cases in which a relation to secondary disorders can be proved. Tonsillectomy is always advisable in those patients in whom the diseased tonsils cause frequent relapses. Like most internists, the author thinks that tonsillectomy should not be done during an acute attack, but that from four to six weeks should elapse after an attack before it is done. An early operation is advisable only when the sequelae in internal organs are constantly renewed from the tonsillar focus, or when there is danger of sepsis. It should not be overlooked that early operations may lead to serious exacerbations of arthritis, scurica, nephritis or other disorders. Tonsillectomy, when performed after the acute manifestations of the disease have disappeared, as for instance in relapsing tonsillitis, in acute articular rheumatism and after a nephritis, has only prophylactic value. In chronic nephritis, tonsillectomy is not advisable. Occasionally severe complications such as pneumonia or sepsis develop after removal of the tonsils, and even fatalities have been observed. This is another reason why indications and time for tonsillectomy should be carefully considered.

Mice as Indicators of Presence of Carcinogenic Noxae

Teutschlaender states that a mouse that had been caught in a briquet factory had numerous tumors and warts. Microscopic examination of the tumors revealed that they were squamous cell epitheliomas, and the warts were found to be precancerous formations. The growths were like the tar or pitch cancers that are produced experimentally by the application of tar to the skin of mice. That the growths had been caused by pitch dust is proved by their morphologic identity with the pitch warts and pitch cancers in some of the workers of the factory as well as by the presence of pitch dust in the fur of the animal and by blackish pigment in the Kupffer cells in the liver. The spontaneous pitch cancer in the mouse indicated the presence of carcinogenic noxae in the factory. The author thinks that since a mouse develops cancer after being exposed only for several months, while in human beings cancer develops only after several years of exposure, it would be advisable to keep white mice as controls in factories in which gas or dust is present, the pathogenicity of which cannot be absolutely denied. The careful examination of the mice after a certain time of exposure would reveal whether noxae are present or not or whether the protective measures are effective. In so-called cancer houses, that is, in dwellings which rightly or wrongly are reputed to cause cancer in those who live in them, cages with mice should likewise be kept. In this manner not only could the etiology of cancer be investigated but it would also be possible to take prophylactic measures. The author comes to the conclusion that, since it is possible to prove the existence of cancerous noxae in a factory before a human being develops cancer simply by keeping control mice, it is no longer pardonable to omit this experiment and wait until the workers develop cancer.

Differential Diagnosis Between Myeloid Leukemia and Cancerous Metastases—Erdstein and Kienbock report the case of a woman aged 51. Before she came under their observation she had been examined by several physicians. On the basis of the symptoms her ailment had been diagnosed as pernicious anemia and following a blood count leukemia was thought of. The roentgen examination finally revealed cancerous metastases in the lymph nodes and in the lungs. The authors point out that the differential diagnosis between myeloid leukemia and cancer metastases is sometimes difficult, because some cancers cause an irritation of the bone marrow and thus lead to leukocytosis. Roentgenoscopy of the thoracic organs is often helpful in detecting metastases. However, neither the blood picture nor roentgenoscopy is helpful in determining the hidden primary tumor.

Mitteilungen a d Grenzgeb d Med u Chir, Jena

42 143 262 (Dec 18) 1930

- Vermiform Appendix Pathology of Motor Apparatus. R. Rossle—p 143
*Infantile Hereditary Thrombasthenia. A. Fomio—p 166
*Changes in Vertebrae in Carcinosis. A. Scholtz—p 178
*Staphylococcal Sepsis. Clinical Aspect and Treatment. W. Felsenthal—p 185

Infantile Hereditary Thrombasthenia Blood Status and Coagulation—Fomio reports a case of infantile hereditary thrombasthenia (Glanzmann) in a child aged 4 years. The number of blood plates was increased from 250,000 to 700,000, the bleeding time was prolonged and the retractility of the blood clot was decreased. The disturbance of coagulation lay in the third phase and was caused by an insufficiency of the individual blood plate. The first and second phases of coagulation proceeded in the normal manner. The thrombocytosis represented an attempt on the part of the bone marrow to compensate for the insufficiency of the blood plates. The insufficiency was apparent in dry smear preparations. The blood plates were distributed regularly over the field of vision as in a magnesium sulphate preparation. The complete absence of clumping indicated athrombosis. The blood plates were round or oval and sharply outlined forms, drop forms and projections, which are considered manifestations of the tendency to clumping, were extremely rare. They were also larger than normal giant forms were present in many variations. The number and arrangement of the granules were variable but in most of them the number was decreased. Many of the blood plates contained vacuoles.

Changes in Vertebrae in Carcinosis—On the basis of his observations in seventeen cases of carcinosis of the vertebrae, Scholtz concludes that in the differentiation of this condition from other pathologic processes with similar manifestations the examination of the intervertebral disks does not always give conclusive results. Carcinosis of the vertebrae is rarely accompanied by a gibbus. In one of the cases a gibbus was produced not by a posterior displacement of the spine of the vertebra but by the tumor. In carcinosis there frequently occurs a uniform compression of the bodies of the vertebrae. The upper and lower cortical plates of the bodies of the vertebrae possess in some of the cases a resistance to the process of destruction. The axis of the vertebral column undergoes a deformation when as the result of the destruction of the upper and lower cortical plates the relation between them and the intervertebral disks which preserves the axis of the spinal column is disturbed.

Staphylococcal Sepsis. Clinical Aspect and Treatment—In sixty-two cases of staphylococcal sepsis studied by Felsenthal the condition was caused by *Staphylococcus pyogenes aureus* fifty-one times and by *Staphylococcus pyogenes albus* eleven times. Fourteen of the patients recovered. The portal of entry of the causal organism was demonstrated in 56 per cent of the cases. In 72.58 per cent of the patients it was in the form of an injury of the skin, furuncle or paronychia.

in 20.97 per cent it was located on a mucous membrane (endometrium, oral mucosa, nasal mucosa, urinary tract, tonsils) and in 6.45 per cent it could not be found. The location of the focus of sepsis was only slightly dependent on the portal of entry. The points of predilection for the localization of the causal organisms were the bone marrow (29 per cent) and the endocardium (19.4 per cent). Previous healed pathologic conditions of the endocardium and the valves of the heart did not predispose to a subsequent localization of the bacteria on them. In some of the cases the focus of infection was an abscess in the lung. In 17.7 per cent of these cases there was present endophlebitis of the branches of the pulmonary veins and secondary foci of infection. One of the characteristics of the streptococcus is its great tendency to produce metastases; these were present in fifty-eight of the patients. The organ most frequently involved was the kidney, but the elimination of the organism through the bile and sputum resulted also in metastatic involvement of the liver and lungs. The severity of the condition was dependent on the location of the primary focus and the location and number of metastases. In the treatment of the condition, a silver preparation was used in sixteen cases with two recoveries and morphine in twenty cases with two recoveries. Protein therapy proved ineffective in four cases and autovaccines in five cases. Surgical treatment was used in twenty-seven cases with nine recoveries. The results were particularly good following the surgical treatment of foci of infection in the extremities and following drainage in pleural empyema.

Action of Hypertonic Solutions of Sugar in Toxicosis

—In the treatment of a large number of infants with toxicosis, Choremis compared the effects of subcutaneous injections of hypertonic and of isotonic solutions of dextrose. In infants who had formerly lost a great deal of weight (from 400 to 500 Gm. in twenty-four hours), regardless of whether they were in a markedly toxic condition or not, it was noted that from ten to fifteen minutes following the subcutaneous injection of from 80 to 100 cc. of a 10 or 15 per cent solution of dextrose the infants became extremely restless and could not sleep. In the severe form of reaction, of which three instances were observed, motor unrest and even convulsions appeared. The infants became pale and had cold sweats, labored respiration and an exacerbation in their general condition. The pulse was small and filiform. In one case, meningeal manifestations appeared and the general condition of the patient became much worse. The same changes were noted in atrophic children following subcutaneous injections of a hypertonic solution of dextrose and were in marked contrast to the effects produced by subcutaneous injections of an isotonic solution of dextrose. From ten to fifteen minutes following the injection of an isotonic solution of dextrose the infants became quieter, slightly apathetic and sleepy. This condition lasted two or three hours. The author believes that the harmful effects of subcutaneous injections of hypertonic solutions of dextrose in toxicosis are the result of their osmotic action from the already dehydrated organism still more water is withdrawn and the result is an intensification of the exsiccosis. In the treatment of toxicosis in infants by means of subcutaneous injections of a solution of dextrose he now uses only an isotonic solution.

Blood Picture in Initial Fever in Tuberculosis—Arany designates initial fever in tuberculosis as the fever that appears between the time the infection is incurred and the time the

tuberculin reaction becomes positive. The average incubation period is from three to seven weeks and the fever lasts from four to eight, more rarely from fifteen to twenty, days. In the examination of the blood of five children during this period it was found that in all five there was a slight leukocytosis, absolute and relative neutrophilia and lymphopenia. The neutrophils showed degenerative changes (variations in the granulation of the cells, toxic granulation, vacuoles in the plasma and markedly pyknotic nuclei). The changes were not as well developed as those that are noted in septic conditions but were definite. Whereas in the leukocytic formula the regenerative displacement was slight, in the erythrocytes the polychromasia and basophil granulation were more marked than they were in the common infections of children.

Concurrence of Different Forms of Tuberculosis in Twins—Stramm cites an instance of the concurrence of different forms of tuberculosis in a pair of binocular twins. The two infants had been exposed to the same source of infection. The one developed a tuberculosis of the lung and hilus together with an erythema nodosum and the other developed a miliary tuberculosis. In the first infant the tuberculin reaction was strongly positive but in the second infant it was negative. The negative tuberculin reaction in the infant with the miliary tuberculosis is explained by the development of an anergy such as is noted in measles.

Simple Formula for Calculating Normal Body Weight of Children—For calculating the normal body weight of children aged from 1 to 12 years, Herrmann recommends the formula $y = 2z + 8$, in which y is the body weight in kilograms and z the age of the child in years.

- *Mode of Action of Commonly Used Depilatories. L. Abramson —p. 2187

Postoperative Peptic Ulcer of Jejunum—Fohl asserts that the postoperative peptic ulcer is most frequent after gastric enterostomies. Hyperacidity is also an essential factor, for hyperacidity and in anacidity, peptic ulcers are not noted after gastroenterostomy. However, gastroenterostomy is not the only operation that leads to peptic ulcer of the jejunum. The exclusion of the pylorus according to von Eiselsberg's method may likewise be followed by it. In fact, not a single method of resection excludes the possibility of a postoperative peptic ulcer. The first method of Billroth is perhaps the method after which peptic ulcers are rarest. The only real protection against peptic ulcers in the jejunum is gastroduodenostomy, because this operation does not expose the jejunum to hyperacidity. The diagnosis of postoperative peptic ulcer of the jejunum is difficult because of the absence of a pathognomonic sign. In many cases the symptoms are the same as those in cases of gastric or duodenal ulcer. However, if the anamnesis reveals that a gastric enterostomy or an exclusion of the pylorus has been done before the following signs indicate a peptic ulcer of the jejunum: (1) localized deep pain in the left mesogastric region, (2) occult or spontaneous hemorrhages, (3) dynamic disturbances in the evacuation of the stomach and intestine and occasional vomiting. In regard to the treatment of the postoperative jejunal ulcer the author states that conservative treatment is never advisable and surgical treatment should be given immediately. There is no special operative method for the postoperative peptic ulcer. The surgical treatment is always corrective, and its aim should be not only to remove the ulcer but also to correct the abnormal anatomic conditions created in the first operation. The author discusses several possibilities and then gives the detailed report of one case. The operative mortality is of course comparatively high, however, if the operation is successful, the prospects for permanent results are good. In order to prevent postoperative

ulcer it is of greatest significance not to perform a gastro-enterostomy or an exclusion of the pylorus when hyperacidity exists

Methods of Cervical Dilation and Treatment of Abortion—Of the various methods that are employed for dilation of the cervix uteri Bardeenheuer mentions metal dilators, laminaria tents, tamponade, metrectrics, surgical interventions such as incision of the os uteri or of the cervix, and digital dilation. The numerous methods show that there is a difference whether the dilation is performed during the nonpregnant condition, in the early months of pregnancy or in the later months of pregnancy. The author discusses mainly the treatment of abortion and of premature births. In the nonclimical treatment of abortion, vaginal tamponade is generally done. However, it has the disadvantage that the stasis caused by the tamponade may lead to infection. For this reason the tamponade should never be maintained longer than twelve hours. The author further discusses the advantages and disadvantages of laminaria tents. Dilation by means of the metrectric he considers as one of the best methods. He employed it in forty-two cases, namely, in twenty-five abortions, in five interruptions and in twelve cases of dysmenorrhea or for exploration of the uterus. The metrectric and its manipulation are described, and it is stated that the use of this instrument produces regular uterine contractions. In from six to fifteen hours the cervical canal has been dilated so that it is passable for one or two fingers. The main advantage of this method over tamponade or over the use of tents is that it permits the continuous discharge of uterine excretions. In several cases it was noted that the fetus or the placenta had been discharged through the open blades of the instrument into the vagina. The author advises against ambulatory use of this method, because rest in bed is necessary. However, the metrectric may safely be employed by the general practitioner in the private home.

Mode of Action of Commonly Used Depilatories—Abramson points out that for most depilatories the claim is made that they have a more lasting effect than shaving and that if they are used systematically for a longer period they will effect a permanent depilation without injuring the skin. The author investigated the mode of action of depilatories on animals and on human beings. He found that the depilatories do not influence the intracutaneous portion of the hair but that they become effective by a process of swelling which after from five to ten minutes makes the hairs brittle, so that they break off. The horny layer of the skin is at first not injured. However, after several applications inflammation and eczematization sets in. In their effect on the growth of the hair the depilatories do not differ from shaving. An increased growth of hair after one or several applications could not be detected when compared with shaving. On account of the eczematization of the skin that follows after repeated applications, the use of depilatories for therapeutic purposes should be limited. Depilatories may be used (1) for depilation in regions that are not readily accessible for razor and scissors, as for instance in the axilla, (2) in diseases of the skin or hair in which removal of hair is therapeutically desirable but in which shaving is not advisable, for instance, in folliculitis barbae et capitis. In trichophytosis of the head or of the beard, depilatories might be better than shaving because they prevent more effectively a spreading of fungi and a reinfection of the hairs. However, in both cases depilation is usually insufficient.

Nature and Various Forms of Angiomatosis K. Ullmann—p 1538
Tuberculosis in Nurslings A. Gotz—p 1542
Idem. S. Feilendorf—p 1543

Operative Treatment of Goiter—Breitner thinks that surgical treatment is not resorted to often enough or it is used too late. At any rate these mistakes are more frequent than the premature or unnecessary performance of an operation. Surgical treatment is absolutely necessary in goiters that cause

stenosis. Three cases are reported that illustrate how much needless suffering is due to a delayed surgical intervention. In cases of goiter in which a hypertrophication of the thyroid exists surgical treatment is indicated whenever a conservative treatment of the thyrotoxic manifestations is without effect or when frequent relapses occur. In regard to iodine therapy the author states that in thyrotoxic conditions iodine therapy is not advisable; however, administration of iodine preparatory to operations is helpful. The method of operation and the skill of the surgeon are of the greatest significance. Unilateral resection is not advisable. For especially difficult cases the author recommends the incomplete operation according to Crile. However, if operation is preceded by iodine therapy, this is rarely necessary. The duration of the operation is of greatest significance. Greater rapidity gives the better result.

Existence of Hypotensive Pancreatic Hormone—Gley and Kisthinos point out that some insulin preparations cause a reduction of the blood pressure. Tests revealed that the substance which reduces the sugar content of the blood does not have the hypotensive effect but that the sugar reducing hormone and the pressure reducing hormone are two different substances, and that insulin preparations which have a blood pressure reducing effect have not been sufficiently purified. The authors point out that it has long been known that the pancreas contains a blood pressure reducing substance, however, they were the first to isolate it. Further efforts were made to determine the nature of the blood pressure reducing substance. It was found that its effect is not due to the presence of choline, histamine or peptone but that the pancreatic hypotensive substance is capable of neutralizing the hypertensive action of epinephrine. It was also noted that the acute pulmonary edema that develops in animals that have been poisoned with epinephrine does not develop if the animals have been protected by an injection of the blood pressure reducing, pancreatic hormone.

Sepsis Problem P. Saxl—p 1571
Pharmacotherapy During Childhood H. Januschke—p 1572

Obstetric Shock—Alders limits the term obstetric shock to a condition that is usually characterized by paleness, cyanosis, fainting, decreased blood pressure, profuse perspiration and air hunger, and which develops one or several hours after labor without there being an anatomic foundation and without immediately preceding mechanical or chemical irritation, but caused only by a spontaneous change in the distribution of the blood. This disease corresponds to the condition that surgeons term secondary wound shock. The author does not wish to combine in the term obstetric shock all shock conditions regardless of etiology, that develop after labor, but he wishes to distinguish between shock after labor and obstetric shock. He mentions the various conditions to which the term should not be applied. The exclusion of all these conditions limits the term obstetric shock to rare cases. In an obstetric clinic in Vienna, among 24,800 confinements there were only six such cases. However, this number applies to severe cases, and it is possible that obstetric shock of minor severity is more frequent. The author gives several case reports and then discusses the pathogenesis of obstetric shock. He thinks that obstetric shock is a manifestation of toxicity due to products of decomposition of proteins in short, a toxic wound shock. For the treatment of obstetric shock he recommends blood transfusion or intravenous injection of from 300 to 500 cc of a 10 to 20 per cent solution of dextrose.

Remedies of Apparently Antagonistic Action in Treatment of Gastric Disturbances—Von Friedrich points out that generally when several remedies are used together the effect of synergistic action are combined. Remedies with an antagonistic action or with an apparently antagonistic action are rarely used together. However, such combinations are not entirely unknown. Von Noorden and Salomon for instance recommend the combined use of hydrochloric acid and sodium carbonate in

subacidity and anacidity when the patient is troubled with heartburn. The author describes another example of antagonistic therapy. In some instances of gastric catarrh in which the roentgen examination gives negative results and in which subacidity or anacidity exists and pathologic changes in the gall-bladder may be excluded the patients frequently complain of pain in the epigastric region and behind the sternum, immediately after eating. Medication with hydrochloric acid and pepsin is often not sufficient because the pains are extremely persistent. In such instances the author attempted the combined application of hydrochloric acid and atropine. These two medicaments appear to work antagonistically. The solution of hydrochloric acid and pepsin serves as a substitute for the deficient gastric secretion. It is known that atropine by its influence on the vagus suppresses the gastric secretion. However, the author found that small doses of atropine cause a temporary stimulation of the muscles of the stomach without influencing the function of the pylorus and the gastric secretion is likewise not influenced. The small doses of atropine should be taken before the meal, whereas hydrochloric acid should be taken in large doses during the meal. Dietary and other therapeutic aids do not become superfluous as a result of this therapy.

- Hereditary Transmission of Tendency to Twin Pregnancy G Dahlberg—p 136

Pyemia Ligation of Veins—Martens discusses the results he has obtained in the treatment of puerperal pyemia by means of venous ligation. He believes that puerperal pyemia is caused by a septic thrombophlebitis. The diagnosis is made on the basis of the anamnesis, the temperature curve, the pulse curve, the blood picture (shifting to the left), the thrombocytopenia, the erythrocyte sedimentation speed, the decreased hemoglobin content of the blood, the general condition of the patient and the results of palpation. At times the positive demonstration of the continuous and increasing bacterial content of the blood is of value but the negative observation is not. Because of the inefficacy of all other forms of treatment and the rarity of spontaneous recoveries, venous ligation should be performed as soon as the diagnosis is made. The extraperitoneal procedure is to be preferred. As a rule the extirpation of the diseased veins is unnecessary. Concurrent parametric or periphlebotic abscesses and phlegmons should be opened and drained when the veins are ligated. If it is evident that the involvement is unilateral, the veins of only one side should be ligated, particularly if the general condition of the patient is poor. If, however, the pyemia continues following unilateral ligation, another operation should be performed and the veins on the other side should be ligated. The operation is not contraindicated even in the presence of metastases.

Leukocyte Picture in Puerperium—According to Fruvet, labor produces a leukocytosis accompanied by acidosis. The most noteworthy feature of the leukocytosis is the increase in the polymorphonuclears, which in most of the cases show a marked shifting to the left. The number of lymphocytes and eosinophils is greatly decreased. After a few days the number of polymorphonuclear leukocytes returns to normal and the number of eosinophils is increased. In the first four days the number of neutrophils and lymphocytes shows a relative increase but by the end of that time the number has returned to normal. From the fifth day the reaction of the blood is normal but the blood picture shows a marked lymphocytosis for a few days. The causes of these changes are the retrogressive processes in the uterus which impose increased demands on the mesenchyme and the lymphocytic elements of the peripheral blood. These changes represent what occurs under completely normal conditions. Emphasis is laid on the extremely delicate reaction capacity of the blood and on the fact that slight disturbances in

the puerperium are frequently accompanied by marked variations in the blood picture. This fact should be given particular consideration with reference to the prognostic significance of the blood picture in the puerperium.

Puerperal Fever Prognostic and Diagnostic Significance of Chills—Schäfer asserts that the occurrence of only one or two chills in puerperal fever is of favorable prognostic import because they indicate a reaction in which the infection is rapidly overcome. Beginning with the third chill, the mortality increases. The number of chills varies within wide limits. The longer the time that elapses before the appearance of the first chill, the more favorable is the prognosis. If the series of chills does not begin until after the first week post partum, the mortality is extremely low. The more frequent and longer the intervals are between the chills, the lower is the mortality. A fever that persists during the intervals between the chills is not of diagnostic or prognostic significance. As a basis for comparison of the pulse curve, a pulse rate of 120 is given. The chill is neither a specific symptom of pure pyemia nor proof of the absence of sepsis. A large proportion (30 per cent of average) of all puerperal infections extend simultaneously through the lymphatics and through the blood. With an increasingly large number of chills, a hematogenous extension becomes more and more probable. When the number of chills exceeds ten it is probable that an originally purely pyemic process has become converted into a septic one by inflammatory erosion of the walls of the blood vessels. The number of the chills and their sequelae are not dependent on the kind of bacteria present. Manual separation of the placenta and palpations during the puerperium cause a high percentage of pyemic processes.

- *Ureteral Calculi Conservative Treatment I S Tschernjak—p 1
- *Metastatic Carcinoma of Bladder G Bodon—p 40
- Phimosia Plastic Operation E Sereghy—p 48

Ureteral Calculi Conservative Treatment—On the basis of the good results he obtained with solution of calculi in nine of eleven cases of ureteral calculi and the unsatisfactory results in three cases of calculi of the renal pelvis, Tschernjak concludes that, since this preparation increases peristalsis in the ureters and produces peristalsis in cases in which the strength of the muscle has been exhausted it is a highly valuable and the treatment of ureteral calculi that are not too large. Under its influence there occurs an increased elimination of salts and other pathologic products out of the urinary tract. Solution of calculi does not have an appreciable action on calculi in the pelvis of the kidney. In the treatment of ureteral calculi the solution of calculi one must consider the tonus of the smooth muscle, which is under the influence of the sympathetic nervous system, and modify it with morphine, camphor and atropine preparations. The injections may be given close together or long intervals. Solution of calculi may be given prophylactically following the removal of calculi from the pelvis of the kidney and should be tried also in stasis manifestations in the pelvis of the kidney and in atony of the ureter.

Metastatic Carcinoma of Bladder—Bodon emphasizes the extreme rarity of cancer of the bladder secondary to cancer of a distant organ. He reports the case of a woman, aged 50, whose left breast had been amputated five years previously for cancer. Two weeks after admission to the hospital she died under the signs of increasing cardiac weakness. Postmortem examination revealed that the bladder was enlarged. In the mucosa there were numerous white, slightly projecting cancer nodules with many small hemorrhages chiefly on the edge of the nodules. Numerous tumor nodules were present also in other parts of the body. From the macroscopic picture it is clear that all the cancer nodules were metastases from the cancer of the breast that had been removed five years previously. Microscopic examination revealed that the metastasis to the bladder had occurred through the lymphatics. From the bladder the cancer had extended to the axillary and pectoral lymph nodes. From here the tumor cells had passed through connecting lymphatics into the bronchial and tracheal lymph nodes and from these to the nodes at the arch of the aorta. The tumor

had then extended retrogradely through the retroperitoneal aortic lymph nodes to the hypogastric nodes. Through the lymphatics of the true pelvis it had extended to the bladder.

- *Case of Traumatic Thrombosis of Portal Vein Terminating in Recovery P Rupprecht—p 3118
- *Double Appendix Is There Such an Entity? W Goldschmidt—p 3123

Trauma and Appendicitis—Licken is not convinced that trauma causes appendicitis. He cites the case of an athlete who sustained a severe jolt of the abdomen, especially on the right side, while performing on an apparatus in the gymnasium. He had seemingly been in good health, except for some discomfort in the right inguinal region and irregularity of bowel movement. Immediately after the accident, he developed symptoms that led to a diagnosis of acute appendicitis, probably of traumatic origin. At the operation the appendix appeared to be quite normal in appearance but not in position. It was of the recessus retro caecalis type with the tip adherent in a peritoneal pocket. The important feature of this case was that when the abdomen was opened a tear extending one third the width of the muscle was found in the right rectus muscle. The sheath of the muscle was intact, but a small hematoma underneath shining through led to the discovery of the tear in the muscle. Further examination of the appendix failed to disclose anything abnormal. The author points out that here is a case in which the trauma might have been charged with producing appendicitis, but there was no appendicitis. The abnormal location of the appendix would account for the symptoms present before the trauma and the rupture of the rectus muscle would account for the subsequent symptoms, although these pointed rather definitely to appendicitis—especially the leukocytosis, the resistance in the McBurney area, and a positive Rovsing sign. Hence it is pointed out, in all cases of abdominal injury it is important to rule out possible injury of the rectus muscle.

Incidence of Carcinoma of the Breast in Married and in Unmarried Women—Pikkaramen quotes figures to show that the incidence of breast carcinoma is relatively greater in unmarried than in married women, at least in Suomi Finland whence Kalima analyzed 600 cases in 1914. The author reviews these 600 cases and adds 505 of his own cases and reaches a similar conclusion but specifies that this applies only to women from 35 upward. In the half decades 25-30 and 30-35 the opposite is the case. He contends, therefore, that lactation cannot be regarded as a contributory cause to the development of breast cancer.

Obesity Associated with Exophthalmic Goiter—Five cases of obesity occurring among eight six cases of exophthalmic goiter are the basis of Portugalow's paper. The ages of the patients varied from 19 to 25. They were all women. He believes that endocrine dysfunction as a whole is the cause of the obesity.

Traumatic Thrombosis of Portal Vein—Rupprecht cites the case of a man who, while caring for a horse, was kicked in the abdomen by the animal and fell into an adjoining stall. He was slightly breathless when on his feet again but returned to his work. Six days later he collapsed losing consciousness. He was taken to the hospital. Examination disclosed extreme distention of the abdomen meteorism in the flanks extreme sensitiveness to touch, ascites increasing rapidly in degree and pain over the spleen. Six liters of fluid was withdrawn. The liver could now be felt to be considerably swollen. Next the legs became edematous and then the scrotum the latter extremely so. The patient also complained of stomach distress. The scrotum became gangrenous and the left testis had to be removed. Within sixty days after the accident the superficial abdominal veins began to distend and eventually a well formed caput medusae was present, the lowermost veins measuring two fingers

in size. The abdominal fluid had to be withdrawn repeatedly for a period of five years the amount withdrawn varying considerably. The greatest quantity of fluid obtained was 36 liters. Finally the ascites ceased and the patient is now, ten years after the accident apparently in good health. No operation was performed, therefore this must have been a case of development of sufficient collateral circulation to take care of the thrombosed portal vein.

Double Appendix—Goldschmidt warns against accepting with too much credulity the statement that a double appendix ever is present. He points out how such a mistake may be made and questions seriously the existence of such an entity. He cites a case in which there was apparently a double appendix but on careful examination it was shown quite definitely that during a previous attack of appendicitis the organ had become attached at its tip to the wall of the cecum and that a pathologic amputation had occurred later, thus leaving seemingly two appendices.

Cesarean Section with Abdominal Amputation of Corpus, Shortly Before or During Labor, in Cases of Impacted Myoma—Samuel stresses that in certain cases of impacted myoma, a cesarean operation with amputation of the corpus uteri is advisable. He illustrates this in three cases. Although the literature contains reports of a number of cases of impacted myomas in which the tumor was born shortly before or during labor so that after the birth took a normal course the author agrees with Albrecht, who states that if at the beginning of labor the myoma obstructs the pelvic inlet or the pelvic canal an expectant attitude is wrong. In such cases the abdominal section is necessary. A vaginal intervention is not advisable. The author asserts that it is wherever possible, even in cervical myomas, to amputate the uterus in such a way that a portion of the uterine mucous membrane remains. This is necessary in order to preserve the regular sexual function.

Influence of Renal Activity on Basal Metabolism During Pregnancy—Krukenberg and Alberts first point out that during pregnancy the basal metabolism is generally somewhat increased. They attempted to determine to what extent the renal activity of pregnant women influences their basal metabolism. Other authors who investigated the metabolism of the kidneys in animals had found that their metabolism amounts to from 7 to 8 per cent of the metabolism of the entire organism. Observations on human beings revealed that the metabolism of the kidneys amounts to from 4 to 6 per cent of that of the entire organism whereas the weight of the kidneys is only 0.6 per cent of the body weight. The authors made their tests on fifty nine pregnant women all of whom were in the advanced stage of pregnancy. In order to accustom the patients to the apparatus the basal metabolism was determined several days before the test. On the day when the experiment was made the women were given 1 liter of weak tea. Several days before the test the diet had been protein free. The authors give a detailed report of three cases with charts showing the basal metabolism the

elimination of water and the specific gravity of the urine. They also give tabular reports of several other cases. They found that during the water test the basal metabolism is increased, and the cause of this is the renal activity.

Intravenous Pyelography in Diagnosis of Renal Tuberculosis—Perlmann asserts that the favorable results of nephrectomy in unilateral renal tuberculosis are largely due to the improved methods of urologic examination. First he discusses cystoscopy and the indigo carmine test. In a large percentage of cases these two diagnostic methods are satisfactory. In other instances they cause difficulties and are therefore not advisable, and in such cases intravenous pyelography has proved helpful. The author gives several case reports which illustrate the significance of pyelography by means of intravenous administration of the contrast medium. This method is helpful in cases of unilateral tuberculosis but it is particularly indicated in bilateral disorders in contracted bladder in case of strictures of the ureters or the urethra and for control examination after unilateral nephrectomies. Intravenous pyelography is without danger for the patient and reveals the anatomic conditions of the urinary tract. However as a functional test it is alone not sufficient and it has to be supplemented by other methods. In patients with tuberculosis of the bladder intravenous pyelography is much less painful than intravesical examination.

Results of Autohemotherapy in Cases of Furunculosis

—Balmagiyaz had used the treatment in ninety boys aged from 10 to 17, pupils of a labor colony. In one group of thirty patients he used treatment with the usual remedies as among others, painting of the furuncles with tincture of iodine, applications of compresses with Buron's solution or of moist and hot poultices. Passive hyperemia and curettage, among others, were used when the furuncle was mature. In another group of thirty patients exclusive treatment with Besredka's antiviral was used and in the remaining group autohemotherapy was tried. The treatment in the first group did not prevent the formation of new furuncles. The effect of the treatment was insignificant in the second group. It also proved to be expensive and inconvenient, since the compresses ought to be renewed every four hours. For the autohemotherapy, the blood was withdrawn from the patient's ulnar vein and injected subcutaneously, usually in the subclavicular region. The blood became resorbed in two or three days, in rare cases the resorption was slow. The amount of blood of a single dose varied from 8 to 22 cc., the total amount of blood injected varied from 8 to 90 cc. In moderate cases, the single dose of blood was from 10 to 20 cc., in severe cases, the dose was increased to at least 15 cc. The injections were usually given at intervals of from two or four days. The autohemotherapy resulted in a rapid healing sometimes within three days. The autohemotherapy was well tolerated, there were neither local nor general reactions. The author stresses that the results were encouraging besides, the treatment is within the reach of every one and therefore can be commonly used.

Pilocarpine for Treatment of Anorexia Nervosa in Children—The pathogenesis of nervous anorexia is not yet ascertained. Nevertheless there is evidence that the fundamental cause of the disease consists in an insufficient irritability of organs controlling secretion of the digestive glands. Therefore the treatment aims to influence the peripheral ends of the secretory nerves. Administration of pilocarpine by the mouth

or subcutaneously increases the secretory activity of the salivary, gastric and intestinal glands and the pancreas as well as the sweat glands. The treatment with pilocarpine was tried in forty-two children, aged from 2 to 10 years, suffering with nervous anorexia. None of the patients presented an organic disease. Pilocarpine hydrochloride was given in the form of a powder, in which it was mixed with sugar, or in an aqueous solution. A single dose varied from 0.001 to 0.003 Gm., it was taken from fifteen to twenty minutes before meals, three times daily for three days. The results, Kazas says, were remarkable. In almost all cases the appetite became normal after three days. Only in two instances was it necessary to repeat the three days' treatment. Pilocarpine has not caused cardiac vascular or respiratory disturbances. Later the pilocarpine was mixed with a 2 per cent solution of hydrochloric acid. The author had not had the opportunity to use the treatment in adults. Cardiac diseases, bronchial asthma and acute respiratory diseases are contraindications for treatment with pilocarpine.

Oldest Description of Ileus. B. Ebbell—p. 1393.

Hemangioma Six Cases—Hartz describes two cases of hemangioma of the retina (von Hippel's disease) in patients aged 17 and 55, respectively, a case of hemangioma in the cerebellum in a boy aged 16, a case of large cavernous hemangioma in the lower end of the spinal cord and cauda equina in a woman aged 41 and also two cases of multiple hemangiomas of the liver in patients aged 36 and 24 respectively.

Slight but Fatal Traumatic Hemorrhages of Brain So-Called Duret Lesions—Berner shows that a slight trauma may cause hemorrhages in the region around the fourth ventricle. He describes the close relation between Duret's lesions and concussion of the brain, discusses the sort of spontaneous hemorrhages in the brain with especial attention to the so-called primary ventricular hemorrhages originating from the choroid plexus or a subependymal blood vessel, and treats of the probability of spontaneous origin of a hemorrhage in the fourth ventricle.

Congenital Myotonia in Brother and Sister—Moe describes almost identical cases in children aged 5½ and 1½ respectively. The musculature of the lower limbs was so hypotonic that the patients could neither stand nor walk. The musculature of the trunk was also affected. In the one there was atrophy of the hips, muscles of the jaw and sternocleidomastoid muscles. During observation for a year, no progression was noted.

RADICAL OPERATIONS FOR MAJOR TRIGEMINAL NEURALGIA

CHARLES H. FRAZIER, M.D., Sc.D.
PHILADELPHIA

From a personal experience with 654 major operations for major trigeminal neuralgia, *tic douloureux*, I am convinced that from every point of view—relief to the patient, the almost total elimination of operative hazards and complications, and the invisible scar—the operation is one from which the surgeon derives greater satisfaction than after any other surgical experience.

In the neurosurgical clinic of the Hospital of the University of Pennsylvania an exceptional opportunity has been afforded to observe neuralgias of the trigeminal system. Ever since Spiller in 1898 proposed section of the sensory root as a substitute for excision of the ganglion of Gasser, I have followed this method and, more because of my associate Dr. Spiller's suggestion than for any other reason, an exceptional number of patients have been referred to this clinic for surgical relief. In this period of approximately thirty years, 1,317 cases of major trigeminal neuralgia have been admitted to the clinic, and of this number the major operation has been performed in 654 cases. During this period the mortality has been reduced to 0.26 per cent.

By "major trigeminal neuralgia" I imply that form of neuralgia otherwise referred to as *tic douloureux*, and I refer to a symptom complex so easily recognized by those familiar with its expression, so definite and unmistakable in its various constituent features that mistakes in diagnosis should be very exceptional. That mistakes may be made once in a while may be admitted when one realizes that there are almost no objective symptoms, except the vasomotor phenomena and the facial spasm. It would be quite possible for a patient familiar with the disease to describe so accurately the features of trigeminal neuralgia that one might with perfect propriety advise and resort to operation.

With an individual experience of 1,317 cases, one would quite naturally draw the conclusion that the disease is not infrequent in the physician's rounds. Such, however, is far from the case. I once inquired of a general practitioner, who at the age of 60 had had an enormous experience in private and hospital practice, how many cases of major trigeminal neuralgia he had seen. He could remember but two. The answer was as I had expected, and there are many practitioners who have never seen a single case. Hence, while contact with the neuralgic patient is a daily experience in our clinic, many a practitioner has had no opportunity to make any observations at all, and it follows, as one would expect, that the successful measures for controlling pain are not matters of common information.

The diagnostic features of major trigeminal neuralgia are so characteristic and distinctive that I shall not dwell on them here but refer the reader to earlier contributions.¹

That one is occasionally puzzled I admit, but under these circumstances a ready diagnostic measure in the alcoholic injection is always at hand. If an effectual alcoholic injection, that is, one which induces anesthesia at once in the zone supplied by the division injected, does not give absolute and immediate relief of pain in the same distribution, whatever form of neuralgia the patient may have and whatever the character and intensity of pain, that patient does not have major trigeminal neuralgia. From this deduction there is no avenue of escape. The term trigeminal neuralgia, or *tic douloureux*, I find is loosely used at times, especially by those who deal with the sinuses. There is no relation between sinus disease and *tic douloureux*, and this is another indisputable statement to which there is no exception.

Nothing can be accomplished by a discussion of the etiology. This discussion would lead only into the field of speculation. It might serve many a future patient a useful purpose to state emphatically that dental and sinus infections are not factors. The teeth should be left alone and the sinuses left undrained.

The major purpose of this contribution is to relate my experience with the 654 major operations. The major operation is not urged on every patient. It is my practice now, as it always has been, to leave to the patient the choice as to whether he shall have an alcoholic injection or submit to the operation. Low as the mortality is, it should be the patient's privilege to decide after he understands fully what may be expected of each.

The first radical operation, excision of the gasserian ganglion, for the relief of trigeminal neuralgia was proposed simultaneously by Krause of Berlin and Hartley of New York in 1894. In 1898 came Spiller's proposal that, as a substitute for excision of the gasserian ganglion, the sensory root of the ganglion be cut. I always liked Van Gehuchten's² paraphrase of this suggestion: "the physiologic extirpation of the ganglion." The first purposeful section of the sensory root for the relief of trigeminal neuralgia was performed in this clinic in 1901.³ Since that time many modifications in the performance of the operation have been made, some of major and some of minor importance. Of the major modifications there are two. In 1915 I practiced for the first time subtotal section of

the sensory root but did not report the results of my experience until 1925.⁴ The fundamental reasons for the introduction of this modification will be found in a subsequent article. The outstanding advantage of this variation in technic, which implied conservation of the ophthalmic portion of the sensory root, was the total elimination of trophic keratitis as a complication. Of this I shall speak later.

The second major modification of the operation was the conservation of the motor root first proposed in 1918 but not referred to in print until 1926.⁵ To

Fig. 1—Area of anesthesia five days after section of the outer third of the sensory root

conserve the innervation of the temporal, masseter and pterygoid muscles has obvious advantages, chiefly these to conserve the power of mastication, to better the cosmetic results and to permit the radical operation on both sides, should the disease be bilateral. That the latter is not a theoretical advantage was dramati-

cally illustrated in a patient from Lima, Peru, on whom I had first operated in 1917. She returned in 1926 with pain on the opposite side. In 1917 the motor root was not conserved and if I did not conserve the motor root at the second operation on the opposite side, the situation would be tragic. As it was my initial experience with such a contingency I urged the patient to have an alcoholic injection. She absolutely refused. I told her she would not be able to close her mouth or chew for the rest of her life if my technic was not perfect, but even then she would not release me. So the operation was performed, the motor root conserved, and all was well.

That the results of the major operation are in the whole eminently satisfactory, a host of patients will testify. With respect to any operation, one must speak of the risk, naturally it is uppermost in the mind of the patient. Desperate as the situation seems, for the pain has become intolerable, the patient's first question is: What are the risks of operation? A direct answer must be given, and if the patient is told that there has been in this clinic but one fatality in the last series of 377 cases, his apprehension on this score is at once relieved. That the operative hazard could be reduced to zero in any large series seems improbable, especially as one is dealing with many patients in the sixties and seventies. In my clinic one patient died ten days after the operation from apoplexy, while another, in the hospital at the same time awaiting operation, died from the same cause. Whether in the hands of many surgeons the subtemporal operation on the sensory root, as recently advocated, will ever be as free from operative hazards as the temporal route, is regarded by those competent to judge as too unreasonable even to answer.

The patient's second question is: Are the results permanent? Since the sensory root in whole or in part cannot undergo regeneration after it is once divided,

the answer is obvious. Frankly I admit on two occasions having overlooked a single fasciculus, once of the second and once of the third distributions, but I rather welcome this opportunity to admit a human imperfection, as I am always somewhat incredulous of the 100 per cent surgeon. In these two cases there was a recurrence, and a second operation was performed. But in principle the operation, perfectly performed, is essentially radical and implies permanent relief. Of this guarantee the patient is often skeptical, so often has he been disappointed by many such assurances by other methods of treatment, inappropriate as they are.

Many patients have been given a lurid account of the operation before they consult the physician. Many a physician today harks back to the operations of the nineties. And his patient has been warned. There is a high mortality, there is a likelihood of facial disfigurement, he may lose the sight of one eye.

Of facial disfigurement there is this to be said. The scar is invisible, but in two cases in a hundred, one may anticipate a transitory facial paresis, which makes its appearance from one to seven days after operation, slow in its development and slow but sure in its recovery. There has been much speculation as to its etiology, and while one cannot speak dogmatically, I am reasonably sure that the paralysis is due to injury to the great superficial petrosal nerve. Furthermore, I think the complication may be avoided if one takes a simple precaution in technic.

In the triangular space posterior to the ganglion, if one elevates the temporal lobe extradurally, one finds the base of the skull still covered with a membrane. Anatomically it is undesignated, but it may be assumed to be a continuation of the envelop of the gasserian ganglion. Underneath this membrane courses the great superficial petrosal nerve, and it is here and here on that the nerve is exposed to injury. Hence one should have respect for this small triangular area and never bare the bone posterior to the ganglion.

Now the question of most concern to the patient misinformed as he so often is has to do with vision. In the early days when total excision of the gasserian ganglion or total section of the sensory root were the routine operations, trophic keratitis was not an uncommon complication, troublesome at best, serious if neglected. But today trophic keratitis is no longer a menace, and the reader must not be misled by statements to the contrary.

It is clearly stated in my article of 1925⁴ that, since I had modified the technic to conserve the ophthalmic portion of the sensory root, keratitis was no longer a complication and when the article was written this modification had been practiced ten years, that is since 1915. Despite the positive character of the statement Dandy⁷ referring to a paper by my associate, Dr. F.

Grant,⁸ states that "with Frazier's subtotal radiculotomy, Grant gives the percentage of cases of keratitis as about 10." Dr Grant wrote, "None of those cases in which the inner upper fasciculus of the root was saved showed any corneal complication." Dandy's statement is so at variance with the presented facts that I take this occasion to call the attention of the profession to the misquotation. Not only is it a matter of scientific interest, but if this impression should prevail among physicians and their patients, there would be needless concern and apprehension about a complication that no longer occurs.

Fig 3—Area of anesthesia seven days after section of the outer two thirds of the sensory root.

At a meeting of the Neurological Society at Baltimore, June 13, 1930, following Dandy's presentation of two patients recently operated on, there was an informal discussion and interchange of views as to the cerebellar approach for tic douloureux. While no corneal ulcer or even a suggestion of corneal injection had devel-

oped before the patients were discharged, nevertheless there were verbal reports of two corneal ulcers after discharge and one of total deafness on the side that had been operated on. Dandy corrected an earlier impression that, by cutting the outer half of the sensory root, objective pain sensation was lost and tactile sensation preserved. What he meant to say was this: that by cutting the outer half of the sensory root the subjective pain of trigeminal neuralgia was cured. In evaluating the relative merits of the accepted temporal route and the proposed cerebellar approach, these statements must be given consideration. Corneal ulcer, and damage to the auditory nerve and to the cerebellum with troublesome ataxia are possible even though occasional complications. But apart from these complications there seemed to be almost unanimity of opinion that the cerebellar approach, if accepted generally as a substitute for the temporal route, would inevitably be attended with a decidedly higher mortality. When dealing with an operation that is one of choice and not of necessity, so far as concerns life, the mortality rate will always be the deciding factor.

I shall not describe the technic of the operation step by step, as this may be found in a recent contribution⁹ but merely make some passing comments which those who perform the operation only occasionally may find helpful.

Often as I have performed the radical operation, I never approach one with any sense of assurance that it will be wholly without technical difficulties. Though operating in a field perfectly familiar in every detail, I find the greatest variation between one case and another. For example, in one case the dura may be unusually thin and so plastered to the skull that it seems impossible to separate it, especially in the temporal region without penetrating it in more places than one. This is not a matter of great moment but it is exceed-

ingly annoying. In the next case one may easily separate the dura and only a moment or two passes before arriving at the foramen spinosum. In one case the course of the posterior branch of the middle meningeal artery is so low that it may be torn as one makes the initial perforation of the skull. In some cases, especially in the dolichocephalic skull the middle fossa is deeper and the ganglion relatively far forward. It is a good plan always to make a perforation in the dura as soon as the cranial opening is made to allow the cerebrospinal fluid to escape. This facilitates the elevation of the temporal lobe, especially in those cases in which there is an unusual amount of fluid in the sub-arachnoid space, and it is surprising how the amount varies.

After he has plugged the foramen spinosum with cotton, and cut the middle meningeal artery and vein—and there is no easier or safer way of controlling hemorrhage from this source than by plugging the foramen—the operator will find it helpful to chisel the small bony eminence that lies just lateral to the foramen ovale. This bony process may be a tiny spicule, a dome-like process, or a ridge. By chiseling it away at once the foramen ovale is exposed to view and this is of great assistance in the presence of a deep temporal fossa. This process is also a sure guide to the location of the foramen, the site of which must be determined before one knows where to look for the cleavage between the dura and the ganglion.

Again, the facility with which the dura may be separated from the ganglion sheath varies greatly. It seems to me sometimes as though there had been a basilar meningitis at some time which not only bound these structures firmly together but extended to the arachnoid and root. Instead of the root lying freely in the subarachnoid space with its several fasciculi easily separated one from the other, arachnoid and fasciculi are more or less fused together and the tissues vascularized, as they are not in the average case.

As the technic prescribes, the operator begins at the foramen ovale to uncover the ganglion and continues as far forward as the point where the maxillary division is given off, and then inward until he can see the pulsating bluish arachnoid, beneath which the sensory root lies. This is the goal. Once the

Fig 4—Area of anesthesia five days after section of the ophthalmic portion of the sensory root in a patient with pain limited to the ophthalmic division.

smallest area of ganglion is exposed I inject a 1 per cent solution of procaine hydrochloride and the ether is discontinued. From conversations and consultations with many patients I have long been convinced that the patient prefers a general anesthetic and in the ether is discontinued at this time the patient is conscious when the wound is closed and has been spared the apprehension of pain which by virtue of years of suffering these patients dread so greatly. I think I know the psychology of the tic patient from every angle.

Following the advice of Oppenheim, Plessner began the use of the drug in the treatment of trigeminal neuralgia, using the inhalation method. After many clinical trials, he came to the conclusion that from 3 to 60 drops could be used three times a day by inhalation without toxic effects, and that from 20 to 30 drops inhaled three times a day would be sufficient to produce complete relief.

In 1916, Plessner³ reported fourteen cases of trigeminal neuralgia treated with trichlorethylene. Of these fourteen cases, twelve were completely relieved and two were unaffected. This first series gave the remarkable result of 85 per cent cured, and it appeared as if a medical specific had been reached for trigeminal neuralgia. However, the later reports of cases did not measure up to the expectations of Plessner. Since the original paper, 163 additional cases of trigeminal neuralgia treated with this drug have been reported, 15 of which are included in the present paper. With Plessner's original cases, the total proportion of complete relief is 25 per cent. Exclusive of his report, the total proportion of complete relief is 15 per cent. As the proportion of complete relief reported by Plessner has not been obtained by other investigators, probably 15 per cent more nearly represents the actual facts. Approximately a further 52 per cent have had partial relief from pain.

From this statistical study it may readily be seen that trichlorethylene, though not giving the original spectacular result, is an extremely valuable adjunct in the treatment of trigeminal neuralgia, provided one is cognizant of its limitations. In addition to these patients with complete relief of pain (15 per cent), this drug has proved quite valuable in the amelioration of symptoms. In the reported cases 51 per cent have had their attacks diminished as to both intensity and frequency. Many of these patients have preferred these occasional mild attacks rather than undergo the even small risk of surgery or have the discomforting effects of anesthesia. In the two included cases in which pain was relieved, one patient had attacks four or five times a day. After two weeks of trichlorethylene therapy, the attacks of pain occurred at intervals of two weeks and were of such mild character that the patient preferred this pain to the anesthesia that resulted from her former alcohol injections. The other patient, a public speaker, developed such severe attacks during his orations that he was frequently forced to stop. After three weeks of trichlorethylene therapy, his attacks became so mild that even if they occurred during a speech he was able to continue. In addition, the frequency of the attacks was greatly lessened.

The question of corneal anesthesia has brought up numerous diversified opinions. Hildsheimer⁴ obtained corneal anesthesia in the majority of cases of non-trigeminal neuralgia, and for this reason recommended the drug in eye diseases. Rohrschneider did not obtain any corneal anesthesia, while Plessner in his original report obtained anesthesia in two out of his four cases. Blumenthal⁵ believed that this drug could be used in vasomotor disturbances of the face, and in vasomotor rhinitis. It was his opinion that the drug acted directly

on the sympathetic fibers, and that the cure was dependent on the presence of sympathetic fibers.

For the treatment of trigeminal neuralgia, the drug should be inhaled three or four times a day, from 20 to 25 drops being placed on a piece of gauze. The inhalation should be continued until the odor has entirely disappeared. This should be carried out over a period of a month to six weeks before its use is discontinued. The drug occasionally produces vertigo, sleep and drowsiness, and therefore it is well to take the inhalation in a recumbent position. After the pain is relieved, it is not necessary to continue the inhalation of the drug daily. As a prophylactic measure, it is extremely wise to inhale this drug every two or three months for a period of three consecutive days. Occasionally the patient may complain of a tingling sensation in the extremities which, however, passes off rapidly. Oljenick⁶ reported a man who began to shriek and sing following inhalation. The best results have been reported in cases of short duration and those involving the mandibular division. Seelert⁷ was of the opinion that trichlorethylene should be given by mouth in gelatin capsules in a dosage of 0.25 Gm. two or three times a day. Bendzulla⁸ believed that its therapeutic

results were obtained more efficiently and more rapidly by inhalation than if given by mouth.

In the original cases reported by Plessner, wherein the toxic effects were noted, trigeminal anesthesia was present. It was this one point of trigeminal anesthesia that led to the use of this drug in the treatment of trigeminal neuralgia. In contradistinction to these original observations, none of these patients inhaling this drug developed any trigeminal anesthesia, even if the pain was relieved. The question of the corneal reflex is still debated. In the fifteen cases reported in this paper no anesthesia was present, nor was the corneal reflex diminished. This was true for the two patients cured and the two relieved as well as for those that were entirely unaffected. Had this drug produced complete bilateral anesthesia of the trigeminal distribution its value for the cure of trigeminal neuralgia would

have been questionable. Such a resulting bilateral anesthesia would have been more discomforting than the original disease, and therefore surgical measures wherein only partial anesthesia of the trigeminal tract could be accomplished would have been the method of choice. As the situation exists at present, a patient cured of trigeminal neuralgia by the use of trichlorethylene has a greater advantage over a surgical cure in that he is free from pain without the resulting anesthesia. The discrepancy existing between the anesthesia occurring in the original workers reported by Plessner and the relief of pain without demonstrable facial anesthesia has led many of the writers, such as von Kalinowski⁹ and Bab, to raise the question whether or not trichlorethylene was the drug responsible for the anesthesia and toxic symptoms reported by Plessner. It has also brought up the point whether trichlorethylene is a specific for the trigeminal tract or whether it acts as a narcotic, depressing the cortex to painful stimuli. These questions are rightly raised. It certainly appears as if the present trichlorethylene is not the drug responsible for the toxic symptoms in Plessner's workers. How it acts on the trigeminal tract is still an unsolved problem.

I have had occasion to try the drug in atypical facial neuralgia and in sphenopalatine and allergic neuralgia, without obtaining any relief from pain. These observations do not favor the cerebral depressant theory.

Trigeminal neuralgia was first recognized by Avicenna in A. D. 1000 and was later described by Schlichtung in 1748. Nicholas Andre, in 1756 for the first time called it "tic douloureux." Fothergill in 1773, was the first to describe the disease accurately, and little can be added to his original description. The diagnosis of trigeminal neuralgia is usually clear cut. The disease consists of superficial, sharp acute, lancinating pain, almost always unilateral and confined to the distribution of the trigeminal tract. This pain usually lasts two or three seconds but occasionally is prolonged to even half an hour with absolute freedom of the severe pain between attacks, with occasionally a feeling of discomfort or soreness in the interim. Frequently there are trigger zones, these being areas which, on being touched, will set off the paroxysm of pain. The pain is never cured spontaneously nor can it be relieved by the usual symptomatic treatment. However, there are frequently remissions when the pain is absent for from several months to several years only to return with more intensity. The etiology of trigeminal neuralgia is unknown, and the attacks may be precipitated by local contact or may occur spontaneously.

A disease which closely simulates trigeminal neuralgia, but which on careful analysis¹⁰ demonstrated many diagnostic differences, is that of "atypical" facial neuralgia. Before this disease was first recognized, the pain was considered that of the trigeminal neuralgia and the patients were subjected to the usual surgical procedure of the neuralgia patients. However, in spite of the anesthetics so obtained, the patients still retained their pain. For want of a better term, this pain was called "atypical facial neuralgia." The pain in this disease is deep seated, deep in the bone, or deep in the muscle, continuous and of tearing, bursting nagging, gnawing nature. The patients have great difficulty in describing the character of the pain, and in a series of

143 cases, 73 different adjectives were used. The pain goes beyond the bounds of the trigeminal tract, extending into the cervical region and occasionally down the arm. It is bilateral in about one third of the cases and has associated with the pain sympathetic phenomena such as lacrimation, edema of the face, congestion of the conjunctiva and flushing of the face. The pain is essentially persistent and continuous. There are, however, periods of greater severity. During the first two or three hours of this aggravated period, the pain greatly increases until a height is reached, after which the intensity slowly subsides until the end of the third day or so, when the chronic phase is resumed. There are many variations from this typical history. There may even be remissions lasting from two to three years.

In addition to atypical facial neuralgia, sphenopalatine neuralgia, neuralgia of the seventh, ninth and tenth cranial nerves, dental pulp stones or allergic headache should not be confused with true trigeminal neuralgia.

The treatment of trigeminal neuralgia is one of surgical advances and progress. It carries with it the names of Rose, Hartley, Liffany, Krause, Horsley, Doven, Spiller, Frazier, Cushing, Dandy and Adson. The first surgery was the removal of the gasserian ganglion by Rose in 1891. He also suggested preservation of the ophthalmic division. Horsley, in 1891, attempted to cut the sensory root of the trigeminal nerve without success. In 1893 the Hartley-Krause operation was introduced. In 1901 Frazier and Spiller reported the first successful intracranial section of the sensory root. In 1896 Liffany suggested the partial section of the gasserian ganglion, and also the saving of the motor root. In 1917 Frazier, after morphologic studies of the gasserian ganglion, and at the suggestion of Spiller carried out the subtotal section of the sensory root. In 1919 Frazier found that it was possible to preserve the motor root. In 1922 Adson suggested the technique of preserving the motor root by exposure from the medial side by gentle traction and elevation of the sensory root. The introduction of the subtotal section eliminated one of the horrifying sequelae that frequently followed the complete section of the sensory root. By the preservation of the ophthalmic division, corneal ulcer could not occur, the preservation of the motor root maintained the motor supply to the muscles of mastication, prevented atrophy of these muscles, and if possible chance bilateral trigeminal neuralgia should occur muscular paralysis need not be feared.

In 1929 Dandy introduced section of the sensory root at the pons and considered this superior to the temporal route. He claimed many advantages by this section from that of the temporal route—namely the preservation of the motor root, the absence of postoperative corneal anesthesia, the larger area of remaining sensation, and the retention of the sense of touch. These advantages are disputed by Gotten, Fay and Grant.¹¹

Alcohol injection of the branches of the trigeminal nerve was carried out by Schlosser in 1903, by Levi and Brudown in 1906 and by Patrick in 1907. Harris in 1912 injected the gasserian ganglion. Treatment by alcohol is only palliative and is of value in patients who are poor operative risks, or in those who are being prepared for the radical procedure. The average duration of relief is about nine months, but occasionally relief is for two to three years.

When the diagnosis of trigeminal neuralgia is definitely ascertained, it would be prudent to try trichlorethylene with the hope that the patient may be among the small percentage so ideally relieved. If this method fails to relieve pain, alcohol injection or surgery should be carried out. It might be well to explain the palliative action of alcohol and the permanence of the surgical treatment. As the operative mortality is only 0.37 per cent, surgery may be safely advised. It is usually found that the patients will first choose the alcohol injection and then with the recurrence of the pain resort to the operative treatment.

REPORT OF CASES

CASE 1—R K, a man aged 56, complained of pain in the left upper and lower gums. He had had all teeth extracted. He had had hypertension with cardiac hypertrophy and angina pectoris for the past several years. About seven months before, he developed attacks of shooting pains in his upper and lower jaws, confined particularly to the inside of his mouth. For several months these attacks had occurred about twenty times a day. They were usually brought on by talking occasionally coming on without any cause. Often rubbing the gums relieved them. The attacks were not of great severity and did not have the appearance of the extremely severe usual trigeminal pain. Roentgenograms of the jaws are entirely negative. Two weeks' therapy with trichlorethylene proved of no avail. Because this pain did not particularly incapacitate the patient, it was deemed wise to block the mandibular and maxillary nerve with procaine hydrochloride. For six hours following this block he was entirely free from pain. The numbness, however, caused him such disturbance that he stated that the pain was much less annoying. For this reason an alcohol injection was not carried out.

This is an extremely unusual case of trigeminal neuralgia and differs greatly from the usual type of cases. However, with this marked relief of pain following nerve block, it is apparent that the diagnosis of trigeminal neuralgia must be made.

CASE 2—H C R, a man, aged 71, complained of right sided facial pain. His teeth had been extracted. About nine years before I saw him, the patient began to have pain in a molar tooth in the right lower jaw. He had several teeth extracted without relief. This pain was of a shooting, sharp, lightning-like character and confined to the right lower jaw. It was brought on by talking, eating or contact. The attacks lasted about one minute and he was free from pain in the intervals. The attacks occurred twenty or thirty times a day. He had eight previous alcohol injections in another clinic. Trichlorethylene did not relieve the pain. Alcohol injection relieved the pain.

CASE 3—T H, a man aged 73 complained of right supra-orbital pain. His family history and past history were essentially negative. Four years before, he developed severe supra-orbital pain, which occurred in attacks lasting a few seconds and were of extreme severity. The pain was of a shooting lightning, tearing character and occurred every few minutes. Between attacks he was entirely free from pain. Trichlorethylene did not prove of value. Evulsion of the supra-orbital nerve relieved the pain.

CASE 4—N T, a woman, aged 51 had right sided facial pain. All her teeth had been extracted. For the past seven years she had had pain on the right side of her face involving the third division of the trigeminal nerve. This pain occurred in attacks lasting two or three minutes and was of a sharp lightning lancing character. Between the attacks she was entirely free from pain. She had had numerous alcohol injections and finally it appeared as if injections would not relieve her pain. Trichlorethylene therapy was tried but it did not relieve the pain. Alcohol injection of the third division was attempted without results. A subtotal section of the trigeminal nerve was performed with a relief of symptoms.

CASE 5—J B, a man aged 78 complained of left sided facial pain. His family history and past history were essen-

tially negative. About fifteen years before he developed severe pain in all divisions of the left trigeminal nerve. During varying periods of time he was pain-free. About eighteen months before the pain returned with extreme severity. It was of a sharp knifelike character, occurring in attacks from thirty to forty times a day and lasting two or three seconds, he was free from pain between attacks. The attacks were so severe that the patient could scarcely eat, was confined to bed and was slowly losing weight. He had six alcohol injections in other clinics the last two proving unsatisfactory. Treatment with trichlorethylene proved of no value. Alcohol injection did not prove satisfactory. He refused surgery.

CASE 6—H K S, a woman aged 78, complained of pain on the right side of the face. About twenty years before the patient noticed the onset of attacks of acute, lancinating pain in the right second and third divisions of her face. These attacks lasted about half a minute and were of extreme severity. During the interim she was entirely free from pain. For the past two years the attacks had occurred in increasing frequency and in the past six months occurred from ten to twenty times a day. There was a definite trigger zone along the border of the nose and the attacks were accentuated by touch or by eating. Treatment with trichlorethylene was tried but proved of no value. Alcohol injection of the second and third divisions relieved the pain.

CASE 7—A L S, a woman, aged 70 complained of left sided facial pain. She had previously had chiropractic and electrical treatment. For the past six years the patient had had attacks of severe sharp, shooting pain on the left side of her face, involving the second and third divisions. In the past year or so this pain occurred about fifteen times a day and in the interim she was entirely pain-free. Alcohol injections relieved her for the past six months. Trichlorethylene did not relieve her pain. An alcohol injection of the second and third divisions proved satisfactory.

CASE 8—F L, a woman, aged 77 complained of pain on the right side of the face. On account of the extreme pain the patient had become addicted to the use of morphine. By sheer will power following the relief of her pain she controlled this habit and for the past eight months had not used any morphine. She had had pain in the face for about forty years the attacks occurring during three or four consecutive years, and occasionally being absent for several years. About nine months before, the pain became extremely severe and occurred practically every day. The pain was gnawing, shooting and knifelike in character, it occurred in attacks lasting about half a minute and brought on by contact or eating. They involved the right second and third divisions. Treatment with trichlorethylene proved of no avail. Alcohol injection of the second division gave relief that has lasted fourteen months, whereas the relief in the third division lasted eight months. The latter was reinjected with the relief of pain.

Morphine addiction in trigeminal neuralgia is a rarity. Frazier has never observed this in any of his series.

CASE 9—A B, a man aged 76 suffered from pain in the face. All his teeth had been extracted. He had had attacks of severe, lancinating pain on the left side of his face for the last thirty years. During this period he had had an absence of pain frequently as long as one year. He would then have a period of severe attacks lasting a week and he would then after be again pain-free. In the last year he had two of the severe periods, one in which the pain was of extreme severity lasted two weeks. He could not sleep nor eat the attacks occurring every five minutes. At the end of the second week period he again had a period during which he was free from pain. About five weeks before he developed another period of extreme pain lasting longer than any he had had. The pain involved the third division on the left side of his face and was of a sharp knifelike character. It occurred spontaneously. Treatment with trichlorethylene proved of no avail. About a month after stopping the use of trichlorethylene his severe attacks subsided. He refused nerve injection or surgery.

CASE 10—M M, a man aged 52 complained of pain in the left side of his face. His family history and past history were essentially negative. For the past several years he

had had attacks of pain involving the left side of his face. These attacks were extremely severe and of a sharp, lancinating character, they would last a few seconds. There were periods lasting from six months to two years in which he did not have these acute attacks, and then he would have a period for several weeks in which the attacks were practically continuous. During these periods he could scarcely sleep and could not eat. He had had no treatment for this neuralgia other than sedatives. He was placed under trichlorethylene therapy without relief of symptoms. Alcohol injection was performed with complete relief.

CASE 11—E V R, a woman, aged 60, complained of right sided facial pain. She had previously had chiropractic and electrical treatment, also, her teeth had been extracted. Off and on for the past year the patient had had attacks of sharp, shooting, knife-like pain situated in the area of the right second division. About eight months before she had an alcohol injection (in another clinic) without relief of pain. Trichlorethylene therapy entirely relieved her pain after three days' administration. Repeated examination of the face failed to reveal any anesthesia; the corneal reflexes were not diminished, nor did the patient complain of any facial numbness.

CASE 12—A S, a man, aged 44, complained of pain in the face. He had had numerous teeth extracted and had had a sinus operation. For the past seven years he had had acute attacks of pain involving the right third division. These attacks would last two or three seconds and were of extreme severity. There were several months wherein he had periods during which the attacks would not occur; then they would occur consecutively in a week or so as often as fifty times a day. He had had previous alcohol injection at another clinic, with the relief of pain lasting from six to eighteen months. Trichlorethylene therapy was carried out without relief. Alcohol injection was successfully performed with relief of symptoms.

CASE 13—C M, a woman, aged 59, complained of pain in the right side of the face. She had had her teeth extracted and had had chiropractic treatment and electrical therapy. The first attack of pain was noticed seventeen years before. She was then free from pain for a period of four years. Alcohol injections from time to time relieved her pain for eighteen months, but the last injection gave her relief for only one month. This pain involved the third division slightly, but was more marked on the second division. Trichlorethylene therapy reduced her attacks, both in severity and in number. She preferred this relief of pain to a total relief which would involve the discomfort of anesthesia.

CASE 14—E B, a woman, aged 70, complained of pain on the right and left sides of the face. She had had all her teeth extracted and had had three sinus operations. Thirteen years before she developed pain in the right third divisions, five years before she developed attacks of acute, lancinating pain in the left second division, and that in the right only occurred occasionally. For the past eight months the pain had been most severe in the second and third divisions of the right side, with only occasional twinges in the left second division. For the past month the attacks had been extremely severe and had occurred from four to five times a day. After one week of trichlorethylene therapy, the pain was completely relieved.

This is an unusual case in that the patient had bilateral trigeminal neuralgia. Operation performed in this case would have been extremely destructive and would have necessitated loss of sensation to both sides of the face.

CASE 15—J M, a man aged 55, complained of pain in the face. He had had several teeth extracted. About a year before, the patient developed pain in the left second and third divisions. These pains were of a sharp lancinating character and of late had occurred three or four times a day, particularly when he talked. He had a definite trigger zone on the side of the nose. Trichlorethylene therapy relieved the pain so that he could continue with his work. The attacks were reduced in number and severity.

CONCLUSIONS

1 The result of a statistical summary shows that approximately 15 per cent of the reported cases of trigeminal neuralgia treated by trichlorethylene therapy were completely relieved of symptoms.

2 The percentage of partial relief varies with the different investigators. In the present series, 13.3 per cent were partially relieved, while in Secler's series 74 per cent were partially relieved.

3 Trichlorethylene therapy is ideal in the treatment of trigeminal neuralgia in those cases in which the drug is effective, as the pain is relieved without a resulting anesthesia.

4 Trichlorethylene is not toxic.

5 The action of trichlorethylene in the relief of trigeminal neuralgia is unknown.

6 It is doubtful that trichlorethylene is the original drug responsible for the toxic symptoms and the anesthesia in Plessner's industrial workers.

DETERMINATION OF THE VALUE
OF ANTISEPTICS*

ABBOTT WILLIAM ALLEN, MD
AND
IRVING SHERWOOD WRIGHT, MD
NEW YORK

It may safely be inferred that the use of antiseptics antedates the earliest existing record of mankind. The preservation of foods in times of plenty for the periods of scarcity was a lesson learned early by prehistoric races. They preserved their foods by dyeing, smoking, salting or spicing.

Spices, volatile oils, and balsams were early used by priests and healers in the care of wounds, although antiseptics was undreamed of. Later certain preparations of mercury and other heavy metals came into common usage. Distilled liquors, potions made from herbs, and even the cautery were listed in the armamentarium of our forebears devoted to the healing of wounds.

Throughout the ages, and until the work of Lister in the latter third of the nineteenth century, the term "antiseptic," however, was associated exclusively with the preservation of foodstuffs. Following his epoch-making discoveries, new and different terms with distinct meanings came into being. Today their use is largely academic. The average physician and surgeon use interchangeably, "antiseptic," "germicide," "disinfectant," and "bacteriostatic."

However, a definition of antiseptics that is most widely accepted at present, and the one recognized by the Department of Agriculture in Washington, was formulated by Reddish.¹ It is as follows:

Antiseptics are substances which, when applied to microorganisms, will render them innocuous either by actually killing them or preventing their growth according to the character of the preparation or the method of application.

From time to time, new preparations with variable bactericidal properties have been produced. This gave rise to a need for evaluating their comparative efficiency. Of the many methods of evaluation suggested, three with modifications are widely accepted today. Of these

the Hygienic Laboratory² and the Rideal-Walker³ procedures are in most common use. The *Lancet*⁴ method is less widely used, especially in this country.

The general principles of the foregoing methods, all devised about two decades ago, are essentially similar. They have individual and common faults, which have become especially evident within the past few years. It becomes obvious to any one working on the subject of antiseptics, from either the practical or the theoretical point of view, that changes in the present technic of evaluating antiseptics are urgent.

The disinfectants in common use at the time these methods were developed were closely allied chemically. They were phenols or derivatives of phenol having, with slight modification, essentially the same properties. Hence it was possible, both theoretically and practically, to compare directly one with the other, using the same single organism for the test. One of the inherent weaknesses of these methods of comparison, the use of a single organism, was less serious at the time of their inception than it is now. Then there was a great need for disinfectants to control epidemics, especially of typhoid. Hence the bacillus of this disease was selected as the test organism for the work. If the variety and cultural characteristics of the bacteria responsible for the infections workers were then seeking to control had been appreciated, some other organism more hardy than *Bacillus typhosus* probably would have been selected as the test organism.

It should be remembered that the methods of testing disinfectants were devised at that time for a purpose quite different from our present needs. The disinfection of inanimate objects contaminated with disease-producing germs was the primary need for the different preparations. Today we are largely concerned with the sterilization of wounds, or the preparation of skin surfaces as germ free as is possible to produce without destruction of tissue. Briefly, then the original methods were devised to compare disinfectants, while our need today is for a system for comparing antiseptics intended for use on living tissues.

The antiseptics of today are no longer simple phenol preparations but include a diverse assortment of alcoholic preparations, heavy metals, complex organic derivatives, dyes and halogens. Their individual bactericidal properties differ in various ways, and their action in clinical dilution depends on a complex group of factors, chief of which might be properly considered the organism with which they come into contact.

In a comparative analysis of the efficacy of antiseptics there are many factors, theoretical as well as practical, to be considered. Of prime importance is the resistance of the different bacteria to the killing action of the preparation in a dilution suitable for clinical use. One antiseptic preparation may kill *B. typhosus* in high dilution and be totally innocuous to staphylococci in the same concentration, as determined by the Rideal-Walker or the Hygienic Laboratory methods, and precisely the reverse may be true as well.⁵ Such information, in terms of the phenol coefficient describing the efficiency of the antiseptic, is not strictly in keeping with clinical results. Hydrogen peroxide for instance, readily killed *Bacillus typhosus* spared *Bacillus subtilis* (a spore former), was moderately efficient in inhibiting

Bacillus pyocyaneus, and was a slighter better bacteriostatic agent for *Staphylococcus aureus*. The statement, therefore, that hydrogen dioxide (which was selected at random⁶) is an efficient antiseptic because it destroys *Bacillus typhosus* expeditiously is, as a matter of fact misleading. It is efficient according to the technic used for *Bacillus typhosus* only. Such an example, however, is illustrative of the situation existing today in connection with antiseptics in general. The resistance of different organisms, representative of bacterial groups and under a variety of conditions to a new antiseptic is usually not even determined before it is put on the market. Furthermore, it is evident that bacteria are not free and isolated in a wound but are intimately associated with the tissues, invading them and often freely intermixed with debris so that they are not readily accessible to the action of the antiseptics. Certain types of bacteria (spore formers) possess a unique protective mechanism which disappears under favorable conditions but retains for the organism its vitality in the presence of deleterious agents. Organisms may develop a fastness to different antiseptics so that they may even grow in the presence of the product which formerly killed them.⁷ There are other preparations that are rendered practically inert on contact with organic matter, so that their action is expended chemically in reacting with the tissues to a greater extent than with the organisms. To overcome these factors without sacrificing the clinical value of the product is still an unsolved problem. However, progress is resulting from the research directed at attaining a reliable antiseptic, germicidal in clinical dilutions, nontoxic, nonirritating, noncorrosive and rapidly efficient.

It is highly desirable that a standard technic for determining the efficiency of an antiseptic under a variety of conditions and using several organisms typifying as nearly as possible the several classes of invaders be adopted. Reddish⁸ says

Phenol coefficients could still be used by the manufacturer for controlling the uniformity of his products, but the dilutions of these products which are specified for actual use must be based on definite tests against the organism it is desired to kill. Antiseptics for use on the skin and mucous membranes and in cuts, abrasions, wounds, etc. should be tested against pyogenic organisms such as *Staphylococcus aureus* and *Streptococcus hemolyticus*. If a disinfectant is recommended for general use, the manufacturer must be sure that the dilutions specified for his product will kill all of the nonsporing organisms which cause diseases of an epidemiologic nature. If he so desires he may recommend only one dilution for general use but he must be certain by actual tests that this dilution will kill those organisms that are dangerous from an epidemiological standpoint. Further, since liquid antiseptics are ordinarily used on the animal and human body are intended to prevent infection by killing pathogenic organisms, especially the pyogenic group or to aid in curing such infections if they have already started, the organisms used for testing their suitability for this purpose should be the ones that are actually met with in practice. It is obvious that the ability of an antiseptic to kill *Bacillus typhosus* the test organism used in our standard phenol coefficient tests is of little value in determining its germicidal efficiency against the organisms causing infections. A phenol coefficient of an antiseptic is naturally of little value to the medical profession and the layman in making a choice from the large number of germicides available.

Among the chief objections to the present procedures, the following may be mentioned. In the method of the Hygienic Laboratory, the broth is too weak, and the hydrogen ion concentration is too high to support a vigorous growth. *Bacillus typhosus*, the test organism, may lose its resistance when grown in these mediums. There is too wide a range of latitude between the phenol dilution and the resistance of *Bacillus typhosus* to it, as determined by the time element. In the original protocol it is stated that the test is applicable only to disinfectants chemically related to phenol which are to be used against organisms reacting similarly to the manner in which typhoid reacts and which are destructible within the time and temperature limits of this test. The usual understanding of the term "phenol coefficient" among manufacturers as well as laymen is that it indicates that the disinfectant is a certain number of times stronger than phenol against all organisms.

In addition to several of the foregoing objections, the Rideal-Walker test has two others of considerable importance. The effectiveness of many disinfectants does not change uniformly with the concentration, so that determination of the coefficient differs according to the concentrations of the disinfectant used. By definition the Rideal-Walker coefficient expresses "strength or efficiency of disinfectants under test" which, in reality, indicates relative strength of disinfectants which will kill *Bacillus typhosus*, as compared with the dilution of phenol, which would kill the same organism under conditions as specified in the test.⁹

From the practical angle, many inadequacies are evident. No notice is taken of the practical application of the antiseptic, which is, in the final analysis, the sole reason for the existence of methods for testing it. The laboratory standard may be summed up in two words: killing time. The clinical applications are not considered. An antiseptic may be suitable for use on the skin, yet unsuited for the eye. Tissue reaction is neglected. A sloughing area needs different treatment than a clean wound. Certain preparations are used as irrigants, others for wet dressings or transient applications. No attention is given to the fact that one of many or even several different organisms may be present against which the antiseptic may have no bacteriostatic action whatever. As far as laboratory procedure is concerned, therefore, with emphasis placed on killing time and the use of an irrelevant weak organism, the practitioner must rely on the trial and error method of evaluation of antiseptics for practical use. Unfortunately, however, there seems to be a great reticence about reporting the unfavorable results, so that the literature contains an unjustifiable preponderance of favorable reports.

Other comparative methods of testing have been suggested by workers from time to time, for a variety of purposes. While these methods may have been open to criticism, especially by those who adhere to the time-honored procedures, the evidence points overwhelmingly to the urgent need for a modern, more comprehensive technic for the comparative rating of antiseptics. The following references support this view. Tinker⁹ and Sutton¹⁰ have collected isolated reports from the literature showing the incidence of nonsterile skin cultures both deep and superficial, following various preoperative skin preparations. It has been suggested that cultures of the skin scrapings be

used to determine the antiseptic efficiency. Weyrauch¹¹ made a comparative study of the phenol coefficient determination of several different antiseptics, using the same technic (the Rideal-Walker) with *Bacillus typhosus* and *Staphylococcus aureus*. The phenol coefficient determination based on the use of *Staphylococcus aureus* differed widely with each antiseptic from the same rating with the use of *Bacillus typhosus*. Reddish¹² and Weyrauch¹¹ and many others have urged the use of several different organisms in any procedure to be accepted. Hailer¹³ showed the variation in the resistance of several different organisms to the bactericidal action of germicides when they were tested by the usual method and when they were suspended on threads of cotton and silk which had been immersed in cultures, in the antiseptic solution. By this method he emphasized the necessity of determining penetrability of the antiseptic. Himebaugh¹⁴ has devised several ingenious experiments to determine irritability of antiseptics to tissue, a feature that should be carefully considered in evaluating antiseptics. Wright and Allen¹⁵ in recent papers have shown the wide variation in bactericidal properties of several antiseptics in the presence of massive infection and superficial contamination. Branham¹⁶ and others demonstrated the fact that antiseptics inhibit the fermentation of sugar by yeast and have urged that the inhibition of the yeast function be used as a guide to the bactericidal action of the different preparations. Richet¹⁷ used the inhibition of lactic acid formation as an index of bacteriostatic action. Thus it is evident that there are many who regard a change in the present system as urgent.

In addition, the following purely practical ideas are offered for consideration.

Manufacturers cannot be held entirely responsible for the making of exorbitant claims for antiseptics which they produce if the standards of evaluation permissible are the methods of two decades ago and the antiseptics of today. The innocent victims of this unfortunate situation are (a) the mass of the public, who have no choice but to believe what is stated plus what is inferred from the advertisements of these products, (b) physicians who are out of touch with the more critical scientific world and hence are in practically the same situation as the lay public in judging values of antiseptics, (c) even outstanding leaders in medicine and surgery who have not sufficient time nor equipment to carry on experimental work either in the laboratory or clinic, to determine for themselves the value of the antiseptics they may desire to use, they may be carried away by the names of a few of their colleagues, or institutions, or manufacturing chemists, whose temporary enthusiasm gives unwarranted support to new and inadequately tested products.

On the other hand, the physician or surgeon who uses the several available antiseptic products is often at fault.

This application of the preparation. This may be the cause of the many unfavorable results noted in connection with the use of some of the antiseptics in common usage today. He must first understand the dynamic pathologic condition at which his medication is directed. Even with the understanding of the problem at hand he may and often does do more harm by medication of the wound than all the germs present would do under ordinary circumstances. Through the use of too strong or too often repeated application of the antiseptic he may destroy normal living and reparative tissues, thereby producing delayed healing, an ulcerating area, an unnecessary slough, or even systemic reactions following the absorption of the toxic products of the tissue degeneration. An agent which inhibits or kills the bacteria present in the wound, but which does not destroy tissue or interfere with the natural defensive body mechanisms, is, generally speaking, far more desirable than one which kills all the organisms present and at the same time accomplishes the destruction of the tissues with which it comes into contact.

It is felt, therefore, that more comprehensive tests are imperative to determine the antiseptic value of a preparation under several different conditions. It is of prime importance that more than one organism be used, as Novy¹⁸ pointed out some years ago. Especially should representatives of the pyogenic group be included, since antiseptics are most commonly directed against them. This point has been emphasized many times during the past ten years, and Reddish⁹ finally formulated a procedure embodying this thought. He reported a comprehensive procedure to the Laboratory Section of the American Public Health Association in 1926 as the culmination of several years' work. His method eliminated many of the objectionable features of the prevailing modifications of the Hygienic Laboratory method and combined their good qualities so that a "phenol coefficient" could be determined with the use of several different organisms, namely, *Bacillus typhosus*, *Staphylococcus aureus*, *Corynebacterium diphtheriae*, *Mycobacterium tuberculosis*, *Diplococcus pneumoniae* and *Streptococcus hemolyticus*. By employing these organisms it is possible to ascertain the action of an antiseptic on organisms typical of the different groups of nonsporulating pathogens. This method is, therefore, superior to the older methods in which only one bacterium was used, one now rarely encountered in the clinical application of antiseptics. This procedure should be used as the first step in the determination of the value of an antiseptic. It will weed out many worthless preparations.

However, there are certain essential characteristics which antiseptics should possess and on which this method and all preceding methods give no information, such as (1) the penetrability of the antiseptic, (2) the action of the antiseptic in the presence of serum, (3) the action of the antiseptic in the presence of massive infection, and (4) the action of the antiseptic on living tissue. These points are adequately estimated by the following methods of testing antiseptics.

In 1924 Himebaugh devised a new method for the testing of antiseptics and germicides, designated as the agar cup plate method. Through the cooperation and kindness of Dr. Himebaugh we were enabled to include his method⁹ in this paper, with several important modifications now published for the first time. After a tremendous amount of experimental work, involving many combinations of different percentages of agar,

added nutrient mediums and blood serum, Dr. Himebaugh believes the formula presented here is the one best suited for all round purposes of this test. The object was to visualize in the laboratory the results that might be obtained when an antiseptic or germicide is applied to open cuts and wounds. For the purpose of representing as nearly as it is possible in the laboratory the colloidal-like body fluids and tissues, standard beef extract agar was selected, containing from 10 to 50 per cent normal blood serum. Although there may be defects in the selection of the mediums it is believed that from the standpoint of food material, salts and blood serum the method is sufficiently accurate for the purpose of indicating the comparative value of antiseptics and germicides when applied to open cuts and wounds over short time periods as well as over long time periods of exposure. As the colloidal-like structure for the mediums, Himebaugh has found standard beef extract agar superior to gelatin. When the amount of blood serum used is 50 per cent by volume, the medium is double strength standard beef extract agar. From 1.5 to 2 per cent agar is capable of indicating to the greatest advantage differences in antiseptic and germicidal value. The test organism selected was a standardized culture of *Staphylococcus aureus*. The resistance of this organism to most germicidal agents is greater under laboratory conditions than that of most other non-spore-bearing pathogenic organisms. It is representative of the pus-producing type of organism encountered in open cuts and wounds.

The technic in running the test is as follows:¹⁰

Standard beef extract agar, 250 cc., in flasks is cooled to a point at which it will not cause coagulation of the blood serum. Blood serum is then added to make 10 per cent concentration. The flasks are immediately inoculated with a twenty-four hour broth culture of the test organism. The inoculation is made by first diluting the culture 1:20,000 and then adding 1 cc. of this dilution to the flasks of medium. Immediately after inoculation and mixing by careful rotating, 30 cc. of the inoculated mediums are then transferred to petri dishes. After the agar is allowed to cool and form a solid jelly, a disk having a diameter of 2 cm. is removed from the center of the petri dishes. The cup or depression thus formed is then sealed at the bottom with a few drops of liquid agar. Originally glass stoppers were used to produce the desired cup. This was found a bad practice, causing injury to the medium at the time the glass stopper is removed. A nickel-plated, specially sharpened cork borer, sterilized in a free flame, has been found most efficient in easily removing the disk from the center of the agar plate. After the medium is allowed to cool and form a solid jelly, 0.5 cc. of the antiseptic or disinfectant to be tested is placed in the cup at the center of the petri dish. If the antiseptic is to be applied for only a short-time period in practice the technic of the test is to remove the antiseptic by means of sterile filter paper after five, ten, fifteen or thirty minutes in the cup. If the method of application recommended indicates that the product would be in constant application with the tissues over a period of time, such as results in the application of wet dressings, antiseptic powders or ointments, the antiseptic or germicide is allowed to remain in the cup for a period of forty-eight hours. The petri dishes, after treatment with the antiseptic or after its removal from the cup or depression at the center are incubated for a period of forty-eight hours at a temperature of 37 C. for the purpose of securing growth of any organisms not inhibited by the antiseptic or germicide. The results are tabulated in distances from the cup showing no growth. A further test is then made to determine whether or not the action observed was inhibitive or germicidal. Small disks (0.1 cc.) are removed from the mediums at distances of 0.1 cm. each until the area where there is visible growth is reached. The disks are transferred to standard beef extract broth in sufficient volume to avoid any inhibitive action and

after breaking up in the mediums are incubated for a further period of forty-eight hours. The results are tabulated, indicating the distances from the cup where the germicidal action was evident from the fact that no growth of the test organism was obtained.

The results of the antiseptic or growth-inhibitive action are photographed or reproduced by photostat in order to preserve a visual indication of the antiseptic or growth-inhibitive action of the sample examined. It is also important to observe and take into consideration the action of the antiseptic or germicide on blood serum. The method as described can be constantly repeated on the same product without variation in results. An additional advantage of this method is the accuracy with which a portrayal of penetrating antiseptic and germicidal effects under conditions simulating as nearly as is possible in the laboratory the application of antiseptics or germicides to broken skin surfaces may be obtained.

The problem of massive infection is frequently confronted in the practical use of antiseptics. We have previously shown that the action of antiseptics in the presence of massive infection may differ widely from their action under the extreme refinements of the present standard methods wherein the organisms are readily available to the action of the antiseptic. Organisms are not commonly found in the relative dilution of the agar cup plate method of Himebaugh. Hence an antiseptic should be tested in the presence of massive infection or contamination. Therefore, the following technic is offered as a modification of that set forth in previous communications. It enjoys the advantage of being more specifically standardized.

Organisms of known virility and resistance to phenol according to the classification of Reddish are used. They are transplanted for three successive days on agar slants of the following composition: Armour's peptone, 10 Gm.; Liebig's beef extract, 5 Gm.; salt, 5 Gm.; agar, 15 Gm.; distilled water, 1,000 cc., adjusted to a pH of 6.8. Five cubic centimeters of the agar is placed in each of the usual $\frac{5}{8}$ by $\frac{5}{8}$ inch lipped test tubes and autoclaved at 20 pounds pressure for one-half hour. Immediately on removal from the sterilizer the tubes are set at an angle of about 15 degrees to the horizon to insure as nearly as possible even and equal slant surfaces, and also to prevent the formation of the undesirable water of condensation which results from the usual remelting and recooling method of preparing the slants.

From the third successive culture a fresh subculture (known as A) of each organism to be used, is made as follows. With a straight nichrome needle, a smear, or at least three streaks, are made on a fresh agar slant (A). This is incubated at 37.5 C for twenty-four hours. At the expiration of this time, 10 cc of the antiseptic to be tested is added to the culture (A). This should be adequate to cover the slant completely when in an upright position. The antiseptic is added at a temperature of 37.5 C. Thenceforth the cultures are maintained at the same temperature by means of a water bath. At intervals of 5, 10, 15, 30 and 60 minutes, transplants from the cultures (A) are made on fresh agar slants (B) or petri plates (mediums as previously described) as follows. With a straight nichrome needle a transplant is removed from the surface of the agar slant (A) and at least three streaks made on the fresh agar (B). This (B) is incubated at 37.5 C for forty-eight hours and then read.

Subcultures (C) are made from all transplants (B) in which there is doubt as to the presence of growth of the organisms.

It is possible to change the time of transplanting from A to B according to the antiseptic used and the accuracy desired. The killing time can be determined more accurately by shortening this transplant time.

The preceding methods have indicated, exclusively, the action of the antiseptic preparation with or without the presence of organic mediums on the organisms under a variety of conditions. However, in practical use, the

bacteria against which the product is used constitute only one part of the whole to be considered. Of what value is a proved antiseptic if in clinical usage its toxicity for tissue is a predominant characteristic? It is necessary, therefore, for a complete evaluation of the product, to determine its effect on living animal tissue, the type with which it will come into contact. Two alternatives are open for investigation: (1) the development of a tissue culture technic in which embryonal muscle and epithelial tissue are used, and (2) direct animal experimentation.

1 By comparing the growth of the tissue to which the antiseptic has been added in clinical dilution with the growth of a similar preparation which lacks the antiseptic, one may determine a phase of tissue toxicity. An additional refinement which might be added would be a similar tissue culture preparation to which a known amount of bacterial inoculation had been added, as well as the antiseptic. This would give a direct comparison of germicidal properties in the presence of a large amount of organic matter and tissue, as well as a simultaneous index of the toxicity of the product toward the tissue.

2 The second phase of tissue reaction, thus far not satisfactorily studied, is that of direct animal experimentation. Many biologic products, several of the drugs, and other alkaloids have been directly standardized by animal tests, so that the clinician has incontrovertible proof of their physiologic action. We may in the future anticipate a somewhat similar result to be derived from a carefully worked out animal experimental procedure to determine the value of antiseptics.

CONCLUSIONS

1 The older standard methods of evaluating antiseptics are not entirely satisfactory as a means of judging modern antiseptics, yet the results with these methods are quoted to prove the great value of products newly introduced.

2 The continuance of the use of *Bacillus typhosus* as a single standard organism to determine the value of antiseptics for use against pyogenic organisms is undesirable.

3 It is highly desirable that each antiseptic, germicide and bacteriostatic preparation should be tested against a variety of representative organisms and under a variety of conditions simulating the conditions these preparations are expected to combat, before they are made available for general use.

4 The determination of the practical value of antiseptics is the only reason for the existence of these tests, yet the present standard methods fail to give satisfactory information on the practical efficacy of the product.

5 Various workers have been striving to correct this situation against strong opposition from advocates of the older methods.

6 This unfortunate situation results in exorbitant claims on the part of the manufacturers, the sufferers being the lay public and also the medical profession.

7 The methods advocated for a complete survey of the value of an antiseptic are as follows: (a) The phenol coefficient method devised by Reddish. This will weed out many worthless preparations and will offer a standard of comparison with former products. (b) The agar cup plate method of Himebaugh. This method demonstrates the penetrating powers of an antiseptic and its activity in the presence of blood serum. (c) The massive infection method described

by us. This determines the activity of the antiseptic in the presence of massive infection.

8 The testing of antiseptics by means of tissue culture and animal experimentation should be added as soon as standardized methods of sufficient accuracy are available.

ANGINA PECTORIS AND DIABETES MELLITUS

HOWARD F. ROOT, M.D.
AND
ASHTON GRAYBIEL, M.D.
BOSTON

When 122 cases of angina pectoris¹ complicating diabetes were analyzed in 1927,² but few other cases for comparison could be found even in such summaries as those of Kahn,³ Levine,⁴ or White.⁵ Since 1927, the association of diabetes and angina has become still more prominent not only in the diabetic clinic at the New England Deaconess Hospital but also among our cases after discharge, so that we are now able to report 210 such cases. Certain features of angina in diabetic patients are sufficiently distinctive to suggest that diabetes may bear an important etiologic relationship to coronary disease and angina.

SELECTION OF CASES

Every patient in this series had paroxysmal attacks of pain or a sense of constriction of the chest. The pain, pressure or sense of constriction was localized in the precordial region or more commonly beneath the sternum with or without radiation to an arm or the neck, was usually brought on by exertion or by emotional excitement, and was relieved by rest, vasodilators or hypnotics. Other types of chest pain were rigidly excluded, and it will be evident from what follows that the cardiac pain in the patients of this series always implied serious organic disease of the heart. Acute coronary thrombosis occurred frequently as a terminal event, but the series was selected to include only those patients with previous attacks of angina.

EPIDEMIOLOGY AND ETIOLOGY

Incidence.—The occurrence of 210 cases of angina in 7,000 cases of diabetes mellitus, exceeding so markedly the incidence of angina in a general hospital population, is the first indication of a specific influence on the part of diabetes. A recent compilation of the causes of death in Joslin's series shows that arteriosclerotic heart disease has risen to first place among all causes of death among 1,250 fatal cases of diabetes in the last four years with an incidence of 23 per cent. The increasing longevity of diabetic patients means longer duration of diabetes as well as advancing age. We believe the incidence to be greater than is accounted for by age alone.

Sex.—A second suggestion of a diabetic influence is afforded by the sex ratio. In this group, 122 were males and 88 were females in contrast to the usually much greater proportion of males. Heberden gave a ratio of 30 to 1, Osler of 7 to 1, and the average proportion in about 1,100 cases compiled from the reports

of Kahn, Schmidt,⁶ Brooks,⁷ Levine, Kahn and Barsky,⁸ and White was 3 males to 1 female. Such a leveling influence on the sex incidence would be expected, since the incidence of diabetes is nearly the same in the two sexes.

Age.—The average age at onset of diabetes was 51 years for both sexes and the average age at onset of angina was 60 years as compared with 57 years in White's nondiabetic series. On the average, diabetes had been present nine years before the onset of angina. In fact, in 188 cases the diabetes preceded the angina, and in only 9 cases did the angina precede the diabetes. In 13 cases the two diseases were discovered at the same time. The average age at onset of the angina is a little greater in the diabetic than in the nondiabetic series, again possibly owing to the fact that the commonest age for the onset of diabetes, in general, is 51 years and, on the average, angina develops from eight to ten years later.

Duration of Diabetes.—A confirmation of the view that the occurrence of angina in the diabetic patient depends on the duration of diabetes is suggested by cases found early in life among young adults with diabetes of long duration. Two cases occurred between 20 and 30 and four between 30 and 40. Three of these six younger patients died suddenly after diabetes of five six and eight years' duration, and in two instances postmortem examination revealed acute coronary thrombosis. The influence of the duration of diabetes may be further demonstrated by comparing the incidence of angina in this series with the incidence by decades of patients having diabetes ten years or more, as shown in table 1. Although diabetes most frequently develops at the age of 51 years diabetic angina occurs most frequently in the decade in which ten year cases of diabetes are most common, namely, the seventh decade.

TABLE 1—Comparison of the Incidence of Diabetic Patients in Successive Decades Ten Years or More After Onset of Diabetes With the Incidence by Decades of Onset of Diabetic and Nondiabetic Angina

Decade Years	Ten Year Cases (Joslin)	Diabetes and Angina	Nondiabetic Angina (Huchard)
0 to 9			
10 to 19	9		3
20 to 29	19	3	5
30 to 39	54	4	44
40 to 49	174	21	87
50 to 59	46	6	7
60 to 69	70	5	4
70 to 79	310	20	27
80 to 89	51		7
Total	1,500	210	277

of life. The contrast with nondiabetic angina is apparent in Huchard's⁹ series in which the decade of greatest incidence is the fifth. The later age of development of angina in the diabetic patient seems to depend on the fact that an exposure to diabetes of several years' duration is an important factor in its etiology.

Symptoms of Diabetes.—In general the character of the diabetes in this series was mild in accordance with the age of the patients. The average carbohydrate in the diet prescribed in the hospital for cases without insulin was 91 Gm. and for cases with insulin it was 93 Gm. The lowest carbohydrate tolerance was 2

¹ Hereafter for brevity's sake angina will be used instead of angina pectoris.

Gm in a case treated before the discovery of insulin and the highest was 223 Gm. The average blood sugar for the entire group was 0.17 per cent. One hundred and twenty-one patients took insulin and the average dose was 13 units. The dietary treatment of this group has varied, but the average duration of diabetes of nine years indicates that in the great majority of cases the onset of diabetes occurred before the discovery of insulin, and especially before the inauguration of modern dietary measures. They serve as a control group for future work. We hope that the use of insulin and diets more nearly normal in their proportions of carbohydrate, protein and fat will in the future prevent the premature development of coronary sclerosis, as recently intimated by Shephardson.¹⁰

Heredity.—Twenty-six patients gave a family history of both diabetes and vascular disease, forty-seven patients, of diabetes without vascular disease, making a total of seventy-three with a diabetic heredity. In seven patients angina had occurred in other members of the family, while in sixty-six patients there was a family history of vascular disease but no angina or diabetes. Thus, ninety-nine patients had an hereditary history of vascular disease.

Hypertension.—Hypertension with a systolic pressure above 150 occurred in 110 patients. It is possible that hypertension was present at some time in a number of the other patients of this series even though blood pressure readings were usually taken on several occasions.

Other Factors.—The average height of the men was 5 feet 7 inches (170 cm), and at their maximum weight they were 25.3 per cent above standard. The average height of the females was 5 feet 2 inches (157.5 cm), and at their maximum weight they were 45 per cent above standard. These figures do not materially differ from those of the diabetic group as a whole. Rheumatic fever was not a predisposing factor. Four patients of 174 had positive Wassermann reactions, making an incidence of 2.3 per cent, as compared with 1.9 per cent for 5,086 diabetic patients given by Joslin.¹¹ One patient had aortitis. Race was of minor importance, thirty-three cases, or 15.7 per cent, occurred among Jews, but in this series of diabetic patients the Jewish race provides 13 per cent of all cases.

PATHOGENESIS

The amount and extent of arteriosclerosis in diabetic subjects that have been examined post mortem is astonishingly great. Every one with a duration of diabetes of five years or more has shown some degree of coronary sclerosis. Actual thrombosis with infarction of the heart, recent or healed, has been present in 25 per cent of 100 autopsies of diabetic subjects at the New England Deaconess Hospital, and in the larger series reported by Warren¹² the incidence of coronary thrombosis with infarction of the heart was 12 per cent. Necropsy in seventy-seven cases of diabetes reported by Blotner¹³ showed marked disease of the coronary vessels in 45 per cent, while in 10 per cent death was due to cardiac infarction. Levine¹⁴ found diabetes present in 14 per cent and Connors¹⁵ in 10 per cent of their cases with coronary thrombosis. Rupture of the

heart occurred twice and aneurysmal dilatation of the wall of the left ventricle twice in the Deaconess Hospital series. This extraordinarily high incidence may be compared with the observations of Benson and Hunter,¹⁶ in whose series of 1,750 patients, most of whom were coroners' cases, coronary infarction plus cardiac aneurysms formed 4 per cent of the whole.

Advanced coronary disease, as well as sclerosis of the myocardium, has been present in every case of angina examined post mortem at the New England Deaconess Hospital. In table 2 is presented a summary of the

† C indicates calcification

observations. The character of the sclerosis and calcification of the coronary arteries was uniform. The coronary arteries are of the muscular type and show changes strikingly similar to the changes found in the muscular arteries of the legs in diabetic gangrene. Evidence of syphilitic or rheumatic infection of valves, myocardium or aorta was absent except in patient 2, who had syphilitic aortitis but more advanced coronary disease. The average weight of the heart in twenty-two patients at autopsy was 386 Gm. The advanced character of the myocardial changes, in spite of the mildness of the anginal attacks, is a distinctive feature clearly shown by the autopsy data. In fact, one wonders how many diabetic patients with undoubtedly marked coronary sclerosis escape having angina.

The electrocardiogram is the best laboratory means of determining coronary disorder before death. Most authors, in reviewing unselected series of angina, have not found this procedure to be helpful in more than 40 per cent of the cases. In fifty cases of this series studied by Dr. J. Lamelas, definite electrocardiographic changes occurred in 60 per cent. Significant inversion of the T wave (coronary type) in leads I or II, or the Pardee¹⁷ sign was present in twenty-three cases. Other observations consisted of two cases of partial atrio-ventricular block, three cases of bundle branch block and two of auricular fibrillation. This emphasizes again the advanced cardiac pathologic change typically found in this series.

SPECIAL POINTS IN TREATMENT

The treatment of angina by the usual drugs and methods is not within the purpose of this paper, but certain aspects of diabetic treatment should be mentioned. Although it is difficult to demonstrate a direct and immediate effect exerted by diabetic treatment on the frequency and character of anginal attacks, a variety of facts indicate that metabolic factors are of importance. Middleton and Oatway¹⁸ found definite depression of the T-wave in 100 per cent of cases of insulin shock with true hypoglycemia. Experimentally Cruickshank¹⁹ found that although the isolated normal heart responds to insulin by storing glycogen, provided the blood sugar is not abnormally low, the diabetic heart stores glycogen only if the blood sugar is maintained well above normal. After diabetes of eight or more years' duration, the heart may become accustomed to an elevated blood sugar. Sudden reductions in the blood sugar brought about by reductions in diet or by insulin are not well borne. In patient 11, fatal coronary thrombosis, proved at autopsy, occurred during insulin hypoglycemia. In Blotner's series, death from cardiac infarction occurred in three cases shortly after a rapid fall in blood sugar concentration following the administration of insulin. By contrast, the relief of attacks when glycosuria and hyperglycemia were controlled by properly adjusted insulin have been reported by Hetenyi.²⁰ The use of dextrose solution, injected intravenously in amounts of 20 cc of a 50 per cent solution, sometimes gives relief when attacks occur frequently, and in one case gave greater subjective comfort than any other means. In one patient, recently, the attacks became less frequent and less severe when, by better adjustment of diet and insulin, the carbohydrate of his diet was slowly increased from 40 to 120 Gm. During coronary thrombosis, especially if congestive failure is present, a marked decrease in carbohydrate tolerance is observed, and the degree of loss parallels the seriousness of the prognosis. However, it is by no means always true that a slight disturbance in the carbohydrate tolerance gives a good cardiac prognosis. In general, with better control of the diabetes, a diminution in the frequency and severity of the anginal attacks is often obtained.

PROGNOSIS

The diabetic patient with angina has a poorer prognosis than the nondiabetic patient. The average duration of life from the first attack of angina to death was only 2 years in the 136 fatal cases. Eighty-five, or 62.5 per cent, of these deaths occurred during the first year after the onset of angina, in contrast with 25 per cent in Gallavardin's series. White²¹ gives the average duration of life in his series of 200 unselected patients as 3.4 years for fatal cases. Mackenzie²² found the average duration of life in 213 fatal cases of angina to be 5.4 years. Improvement in diabetic diets may retard the precocious development of vascular disease in the future.

The patients in our series dying in the first year of angina were those with conspicuously little treatment of diabetes. In contrast are the instances of death after angina of fifteen years' duration, patients 20 and 25. One, a dentist, and the other, a physician

were faithful to the best diabetic treatment available, and as years passed carbohydrate tolerance greatly improved. With present-day diets approaching normal standards, fewer diabetic patients should develop angina and more should survive for as long a period as the nondiabetic.

COMMENT

The association of diabetes, angina and intermittent claudication has been described by Heitz.²³ Is there some single inborn or inherited factor responsible both for diabetes and for a marked susceptibility of the heart to coronary disease and to angina? This conception would make the development of diabetes merely incidental in the life of a patient predestined to coronary disease. One would expect in such combined cases the same sex distribution as in nondiabetic angina, that angina would as frequently precede the diabetes as the reverse, and, because one third of all diabetes originates before the fortieth year of age, that the average age of onset in diabetic angina might be earlier than in nondiabetic cases. On the contrary, however, if the development of angina depends on the existence of clinical diabetes, then the frequency of angina in diabetes would be greater among cases of long duration. The curve of incidence of angina in diabetes would follow not the ages of onset of diabetes, but the curve of cases with diabetes long enough for diabetes to bring about its effects (table 1). The age of greatest frequency of diabetic angina would be the decade in which there is the largest number of persons alive after having diabetes eight or more years, namely, the decade from 60 to 69 years. At present it seems more consistent to regard diabetes and the metabolic changes associated with it as contributing directly to bring about coronary disease, and the inherited factor is that of the diabetic tendency already generally accepted.

For the apparently increasing association of diabetes and angina, the following explanations may be offered.

1 Formerly, the average duration of life of the diabetic patient was too short to permit the full effect of diabetes to be exerted on the coronary vessels and myocardium.

2 The mildness of the attacks, in many cases due to the low nervous sensitivity of diabetic patients or the inactive life they lead, especially under former methods of treatment, gave little evidence until a fatal attack, which in many cases was regarded as diabetic syncope or atypical coma.

3 Formerly, the lack of blood sugar analyses prevented the diagnosis of diabetes. The tendency for an increase in the renal threshold with increasing duration of diabetes may have resulted in the patient's urine being sugar free when his angina was discovered in the cardiac clinic. The use of urine and blood sugar analyses one hour after a full meal and dextrose tolerance tests is often necessary to establish the presence of diabetes, and should be more frequently employed in the study of angina.

SUMMARY AND CONCLUSIONS

1 Two hundred and ten cases of angina complicating diabetes mellitus are reviewed.

2 The incidence of angina in patients with diabetes mellitus is extraordinarily high.

3 The nearly equal sex ratio suggests the lacking influence of the associated diabetes.

4 The occurrence of angina in the young, the long duration of diabetes before the onset of angina and

the late age of onset of angina, all point to the complicating diabetes as the factor that makes this group differ from the nondiabetic series

5 The prognosis for life is shorter than in the non-diabetic series but should improve with modern dietary and insulin treatment

6 Diabetes mellitus with its associated coronary disease is a frequent contributing factor in the production of angina and, like syphilis, its presence should be investigated by special methods, such as blood sugar analyses

81 Bay State Road—Massachusetts General Hospital

DIABETES AND PERNICIOUS ANEMIA

HOWARD F. ROOT, M.D.
BOSTON

The combination of pernicious anemia and diabetes mellitus has been repeatedly described as extremely rare. The first case was reported in 1910 by Parkinson.¹ Within the last two years, nine instances have occurred at the New England Deaconess Hospital, and I have been able to discover a total of forty-eight cases, including unpublished records of patients given to me by other physicians and cases recorded in the literature. The increased interest of physicians inspired by the recent discoveries in the treatment of the two diseases has stimulated diagnosis, but another factor is the increase in the duration of life resulting from improvement in treatment, which affords more opportunity for the combination to occur.

The relative frequency of the two diseases is indicated in tables 1 and 2 by the statistics of Goudsmit² for Holland and by statistics from the Metropolitan Life Insurance Company (New York), prepared by Mr. Herbert Marks.

Since the two diseases are most frequent at approximately the same period of life, there should be a reasonably frequent occurrence of the combination unless there is some specific factor preventing the combination. I have found in the New England Deaconess Hospital series and in the case records of Dr. E. P. Joslin a total of 13 cases in approximately 7,000 cases

In table 3 are listed forty-eight cases. The first thirteen are from the New England Deaconess Hospital diabetic clinic, and the fourteenth from the Peter Bent Brigham Hospital, Boston. The remainder have been abstracted from clinical reports or are reported by courtesy of physicians who have given me their records.

A study of etiologic factors gives various interesting comparisons. The incidence of diabetes is nearly equal in the two sexes, whereas in pernicious anemia males tend to outnumber the females. Of the forty-eight cases in table 3, the males number twenty-four as against twenty-four females. The youngest patient in this series to develop pernicious anemia was 32 and the oldest 70 years of age. Nineteen were between the ages of 45 and 55 years, the period of greatest frequency for the onset of pernicious anemia. The commonest age for the development of diabetes is 51 years. It is notable that in thirty-one cases the diabetes definitely preceded the anemia. In four cases, pernicious anemia occurred first. In the remainder either the diagnoses were discovered at the same time or else the data are incomplete.

Hereditary is increasingly important in any consideration of the etiology of diabetes. In the thirteen cases from the New England Deaconess Hospital, pernicious

anemia was present in the families of three and diabetes was present in the families of five. Conner,⁴ in studying the families of patients with pernicious anemia, has reviewed information indicating the frequency of familial cases and the frequency of achlorhydria in other members of the family. One of Goudsmit's patients with combined diabetes and pernicious anemia had a brother and a sister with diabetes, but the familial data are not available for most of the other thirty-seven cases.

An extraordinary illustration of the familial relationships of diabetes and pernicious anemia is given from the records of Dr. George R. Minot and quoted by Joslin.⁵

Patient, aged 59 years, male, has undoubted pernicious anemia. Brother, aged about 59 years, "has often had sugar in urine and is said to have pernicious anemia with mild cord symptoms." Sister, aged 55 years, "anemic for eight years," undoubted pernicious anemia now. Brother, aged about 50 years, has undoubted diabetes from history given. Brother, aged about 49 years, well. Mother died of diabetes. Father "showed sugar in urine in last illness and died of infected foot that became gangrenous." Father's brother "had anemia and died of it." Father's sister died in thirties of pneumonia. No other brothers or sisters. Mother's sister had diabetes.

Pernicious anemia	301	366	222

of diabetes. Adams³ states that during one period at the Mayo Clinic among 2,000 cases of diabetes and 1,000 cases of pernicious anemia but 3 instances of the combination were observed. Goudsmit² found five cases in Holland among a group consisting of 1,650 cases of diabetes and 379 cases of pernicious anemia seen between 1925 and 1930. It is notable that the great majority of the 48 cases in this series have occurred within recent years, and probably the combination is much more frequent than is generally supposed.

1 Parkinson. Lancet 2: 543 (1910).

Definite information given concerning this Mother's brother died of old age. No other brothers or sisters. Patient's paternal grandfather probably died of pernicious anemia. He was said to have been very pale in last two years of life and had difficulty in walking. An ill-defined history of this man's brother suggests that he had anemia.

Achlorhydria as an etiologic factor in pernicious anemia has been given a new significance by the work of Castle,⁶ who has shown that gastric digestion is defective in pernicious anemia since the stomach is unable to prepare, as it can do normally from protein, a substance effective in alleviating anemia. Immediately this raises the question of the relationship of diabetes and achlorhydria, since in this series the diabetes has so clearly preceded the anemia in most cases. Bowen and Aaron,⁷ Mason,⁸ Joslin⁹ and Rabinowitch¹⁰ have recorded series of observations indicating not only that achlorhydria occurs in from 30 to 40 per cent of diabetic patients but that its frequency tends to increase with the duration of diabetes and the age of the patient. In turn, it must not be forgotten that achlorhydria is much more frequent in healthy old persons than in youth. Conner studied achlorhydria in the families of 110 patients with pernicious anemia and found an increasing incidence of achlorhydria with increasing age, so that between the ages of 50 and 60 years 25 per cent had achlorhydria. The incidence of achlorhydria as observed in the cases of diabetes from the Deaconess Hospital is combined in table 4 with the results of Bowen and Aaron. In 20 per cent of the cases under five years' duration, 35 per cent of those between five and ten years, 45 per cent of those between ten and fifteen years, 29 per cent of those between fifteen and twenty years, and 33 per cent of those between twenty and twenty-five years, there was no free hydrochloric acid.⁹

TABLE 4—Gastric Secretion in Diabetes According to Age of Patient and Duration of Disease

108			34	72	62 or 58 5%	15 or 14 2%	29, or 21 3%

Diabetes of long duration plus achlorhydria may prepare the way for the development of pernicious anemia. The influence of such factors as gallstones and cholecystitis, or other infections is suggested by two cases in which severe anemia (not finally classified as pernicious) developed during observation in the Deaconess Hospital while treatment was being given for severe

infections of the extremities. In both cases repeated transfusions of blood were utilized. Patients 2 and 12 had gallstones, as did Goudsmit's first patient. Patients 3 and 5 had advanced pyorrhea and apical abscesses. Patient 4 had an amputation of the toe for osteomyelitis and developed anemia shortly thereafter. He had one remission and died two years later. A suggestion of diabetic influence is given by patient 14, from the Peter Bent Brigham Hospital, in whom, as severe acidosis developed, a severe degree of anemia rapidly occurred. Also in patient 4, when acidosis developed, his attending physician noted that the anemia was severe and that the blood smear contained many nucleated red cells. This is all the more significant when it is remembered that ordinarily the development of acidosis and dehydration in a diabetic concentration of the blood tends to obscure anemia by giving a relative polycythemia. Furthermore, during a period of severe anemia, the diabetes may also be resistant to treatment, as was noted by Adams.

PATHOLOGY

The pathologic changes of combined diabetes and pernicious anemia have been little studied. Seven autopsies have been found. In Parkinson's patient pernicious anemia preceded the diabetes, which developed rather acutely, and death occurred fifteen days after the onset of diabetic symptoms, apparently from the anemia. Postmortem examination gave the following results:

Deep, red marrow in femur, sternum and ribs. Enlarged spleen. Brown-yellow liver. Chronic gastritis. Bright yellow subcutaneous fat. Small pancreas. No "ugering" of myocardium. Fatty atheromatous flecks in aorta with calcareous plaques. Congestion and severe parenchymatous degeneration of kidneys. Ectopic suprarenal gland. Anemia of brain (3 pounds, 1½ ounces [14 Kg]).

MICROSCOPIC

1 Marrow of femur. Sections were stained by S. G. Scott "tartrazin-Jenner" method in hematoxylin and eosin and in van Gieson's stain. The marrow is cellular throughout. The number of myeloblasts and myelocytes is much in excess of the number of erythroblasts and erythrocytes. Strands of erythroblasts are, however, conspicuous. There are few leukocytes. The megakaryocytes are few in number and of small size. The relative number of myeloblasts to myelocytes is abnormally high. The majority of the erythroblasts are megaloblasts. Gigantoblasts are also present. The variation in the size of the erythrocytes is extreme, microcytes being present in addition to megalocytes and gigantocytes. The erythrocytes also vary in staining reaction. There are a few macrophages containing red corpuscles.

2 Liver. There is no fibrosis. There is a little fatty degeneration of the cells surrounding some of the central veins. In tissue fixed in alcohol there is much granular pigment within the cell columns. This pigment is present throughout the lobules but is much more abundant in the peripheral zone. It gives the Trumbull's blue and prussian blue reactions.

3 Body of pancreas. The lobules do not appear to be abnormally small. The cells of the acini are well formed and brightly stained. There are numerous islands of Langerhans, many of these are of large size. The cells of the islands show no sign of degeneration, they are of normal shape and their nuclear structure is very distinct. There is neither interlobular nor intralobular fibrosis. There is no deposit of pigment.

4 Kidney. The media of the arteries is thin and there is a little reduplication of the elastic lamina. There is no increase in the interstitial tissue. The cells of the first convoluted tubules are large and swollen with well defined margin. The base is occupied by large fat globules. The rest of the proximal plasma is opaque and granular. Many of the cells have no

nucleus, in others the nucleus is pale and degenerate. The swollen cells in most of the tubules almost occlude the lumen, in a few tubules there are granular or vacuolar spherical bodies in the lumen. The cells of the ascending limb of the loop of Henle show very similar changes. In the second convoluted tubules there is much less fatty degeneration, in some there is slight catarrhal desquamation, or the lumen may contain some granular debris. A few fat granules are seen in many of the cells of the descending tubules of Henle and in the large collecting tubules. In many of the latter there is considerable catarrhal desquamation, in others there are hyaline casts. In the cells of the first convoluted tubules are a few fine granules of pigment which give the iron reactions. In the ascending limb of Henle's loop are large granules of yellow pigment which do not give an iron reaction. There is some swelling of the intercapillary substance of the glomeruli. No glycogenic degeneration is present.

To summarize the microscopic appearances of the pancreas and kidney, it may be said that the appearance of the kidney is compatible with a diagnosis of ordinary diabetes or glycosuria and suggests that the pernicious anemia was complicated by diabetes. But the pancreas shows none of the changes found in ordinary diabetes or glycosuria.

A diabetes comparable to that which occurs in hemochromatosis (diabetic bronze) might conceivably be caused by pernicious anemia. Thus, Quincke mentions a case of pernicious anemia in which pigment cirrhosis of the liver occurred. In the present case however, the complete absence of pigmentation and cirrhosis of the pancreas shows that this explanation is untenable.

The necropsy report in the first case of Adams (case 19, table 3) was summarized by him as follows:

There was considerable emaciation, the spleen weighed 312 Gm, its cut surface was brick red, the liver weighed 1787 Gm, the cut surface was yellowish, the stain for iron was positive. The pancreas weighed 68 Gm. There was extreme fatty replacement. The parenchyma was dense and fibrous. The bone marrow was grayish red. A section of the liver revealed slight thickening of the capsule and a fairly marked periportal fibrosis, microscopically. The polygonal cells were faintly stained in areas. Moderate diffuse fatty changes were present. The sinusoids were not distinct and contained small amounts of a yellowish brown pigment. Much of the pigment was distinctly within the Kupffer cells. The iron stain showed this pigment to contain hemosiderin. In the pancreas there was marked atrophy of the acinar tissue, certain areas contained none. The ducts, surrounded by islands lying in a fibrous connective tissue bed, with large spaces of loose fragmentary fibrous tissue, extended in every direction. In other areas there were groups of ducts with no acinar tissue between or around them. In still other areas, small islands of acinar tissue in a loose connective tissue framework, and marked fatty changes. The islands had hyalofibroid changes. In the bone marrow were a moderate number of megaloblasts, numerous normoblasts, and eosinophils. There was no evidence of its normal fatty structure.

Wright's third case (case 27, table 3) was extraordinary in that with modern liver treatment a remarkable remission in the pernicious anemia occurred and polycythemia developed. The patient died with thrombosis of the pulmonary artery. Patient 8 in my series died of gangrene of a foot due to thrombosis and not infection. Thrombosis may have been a factor in causing gangrene in one of Tillgren's cases. Goudsmit mentions postmortem examinations in his second and fifth cases. In the first a small pancreas and large liver were found and in the second hemosiderosis was a conspicuous feature. In Chvostek's case, chronic pancreatitis was found at autopsy. Rabinowitch's first patient (case 33, table 3) showed diffuse fatty degeneration. A remarkable feature during life in this case was the high renal threshold as indicated by a fasting blood sugar of 0.34 per cent without glycosuria.

CLINICAL OBSERVATIONS

The diabetes observed in the forty-six cases cannot be described as differing from the usual forms of the disease. In the Deaconess Hospital series, diabetes was as mild as in the average case of middle life. The blood sugars were of the usual range. All patients in the insulin era did well and developed a tolerance of 100 or more grams of carbohydrate, taking moderate doses of insulin varying from 10 to 30 units a day. Acidosis occurred as a terminal event in one case, and at the time the physician in attendance described a blood smear, showing evidence of severe anemia. The diagnosis of diabetes was in doubt in two cases of pernicious anemia described by Dr I. M. Rabinowitch. In one, the fasting blood sugar was 0.20 per cent, and in the other the maximum was 0.192 per cent when the urine was sugar free. He considers them potential diabetic patients. The first had gallstones. Postmortem examination in the first showed only diffuse fatty degeneration. In general, the degrees of anemia observed were not unusual. In the Deaconess Hospital series the patients for the most part had been under the observation of some physician and were sent for diabetic treatment. The various nervous symptoms had been regarded as due to the diabetes until the anemia was recognized. The diagnostic criteria for pernicious anemia have been the occurrence of recurrent glossitis, symptoms and signs of involvement of the central nervous system, achlorhydria, increased bile pigments in the plasma, with severe anemia of the macrocytic type together with absence of evidence after detailed study of any direct cause for the anemia, and finally rapid decrease of the anemia by the feeding of liver or a potent substitute.

It is notable that periods of exacerbation and severity in one disease usually were accompanied by a similar change in the other. Thus, in the Peter Bent Brigham Hospital case, as the patient developed severe acidosis a rapid increase in anemia occurred, the red blood cells falling in the course of a week from 3,800,000 to 1,900,000 per cubic millimeter. Adams noted in his first case that when the anemia was severe the patient was relatively resistant to insulin. The reverse occurred, however, in patient 10, in whom diabetes was well controlled with 20 units of insulin at the outset of treatment, yet six months later when the red blood count had increased from 2,100,000 to 5,140,000 per cubic millimeter the insulin dose had to be increased to 40 units. This increase in insulin took place without any increase in body weight and with an increase in diet of only 20 Gm of carbohydrate, 21 Gm of protein and 7 Gm of fat.

Evidence of spinal cord changes sufficiently gross to be readily recognized and commented on occurred in fifteen cases. In case 5 the spasticity, rigidity and weakness were so marked in December, 1928 that the patient could not walk, yet with treatment consisting of 300 Gm of liver, 50 grams (3.2 Gm) of pills of ferrous carbonate and 15 units of insulin a day combined with muscle training under the direction of Dr. M. L. Rogers, he left the hospital in three months walking without assistance and giving other evidences of marked improvement. Patient 6 presented a complicated picture. She had had definite transitory attacks of paralysis with hemiplegia and hemianesthesia. She had a speech difficulty not definitely aphasic but apparently a residual of her previous attacks. Prior to these attacks however, she had had paraesthesia, numbness and tingling in both hands with weakness, and both hands had been

had been very cold. She had had attacks of vertigo with nausea and without tinnitus. Her memory for recent events was faulty and she was emotionally unstable. The spinal fluid examination was negative. She made a remarkable improvement in mental and neurologic symptoms with liver treatment and was doing well in July, 1930, nineteen months after she was first treated with liver.

Certain comparisons between the two diseases are of interest. Numbness and tingling found in the hands, feet and legs are common symptoms of both diseases. Yet in more severe stages of involvement of the central nervous system diabetes leads to pain and motor paralysis, whereas pernicious anemia is characterized by spasticity and ataxia associated with subacute combined sclerosis. The changes in the central nervous system due to diabetes, even when pain and paralysis have been present for long periods, usually respond to diabetic treatment, and the patient can be promised recovery.¹¹ The spinal cord lesions of pernicious anemia, when paralysis has occurred on the other hand, improve but rarely return to normal, even with most intensive treatment. Furthermore, during the active stage of diabetic "neuritis" (that is, pain, paralysis of one or more extremities and absence of reflexes) an increase in the total protein of the spinal fluid is often present. Diarrhea is undoubtedly a much more frequent symptom of pernicious anemia than of diabetes, but it is by no means rare in the latter disease, occurring, however, commonly in cases with free hydrochloric acid in the stomach, whereas in pernicious anemia free hydrochloric acid is always absent. Atrophy of the tongue in diabetes frequently produces a typically smooth tongue, but a true glossitis with soreness is rare.

Both diabetes and pernicious anemia tend to produce variations in the lipid contents of the blood, dependent on the stage and severity of the disease. In severe or inadequately treated diabetes a great increase not only in cholesterol but also in lecithin, fatty acid and free fat of the blood occurs. Values as great as 500 to 800 mg of cholesterol per hundred cubic centimeters return to a normal of 220 mg or less, with improvement, and especially with treatment by means of insulin and a diet containing 100 Gm or more of carbohydrate. Bloor¹² noted that the low plasma cholesterol in pernicious anemia improved later. Muller¹³ studied the plasma lipoids of twenty-six cases of true pernicious anemia and eight doubtful cases and found that the abnormally low cholesterol values present during a relapse rose steadily with the onset of a remission. Lecithin values followed those of cholesterol. In a typical case the cholesterol varied between 60 and 70 mg per hundred cubic centimeters before remission, but on the thirteenth day after beginning liver treatment, it reached a normal value of 135 mg.

Claude Bernard¹⁴ first noted that the blood sugar rose in dogs after bleeding, but further observations on the blood sugar in anemia were not made for many years. The behavior of the blood sugar in pernicious anemia presents interesting variations. Johnson¹⁵ found in sixteen cases of pernicious anemia that the fasting blood sugar was above normal and that the blood sugar was higher the lower the hemoglobin. Goudsmit reports eight dextrose tolerance tests using 50 Gm of dextrose

in five typical and three atypical cases of pernicious anemia. In four of the five typical cases and in one of the atypical cases the blood sugar rose above 0.17 per cent. Riddle¹⁶ found a reduction in the fasting blood sugar of patients under treatment with liver extract during early remissions. He interpreted it as due not to an insulin-like substance in the extract but to a metabolic readjustment. Meulengracht and Iversen¹⁷ studied twelve cases of pernicious anemia and found that in severe relapse a high fasting blood sugar occurred as well as an elevated and prolonged blood sugar curve after the ingestion of dextrose. They concluded that these deviations depend more on the intoxication underlying the condition than on the degree of anemia.

Cases of anemia difficult to classify as true pernicious anemia are not rare in the diabetic clinic. Two patients have already been mentioned who, during the course of a severe infection, rapidly developed pronounced anemia, in one of whom hydrochloric acid was absent in the stomach in a single test. In routine examination of blood smears which were checked by an expert hematologist, three cases out of eight were recognized without any knowledge of the patient's condition as probably having achlorhydria, because of suspicious changes in the red blood cells. Mild degrees of anemia are not rare in diabetes, particularly if the diabetes is active and uncontrolled. One wonders whether the absence of anemia among diabetic patients years ago was due to the heavy diets of meat or whether the anemia was not noticed. The fact that under these conditions acidosis and concentration of the blood frequently develop tends to obscure the anemia and so to allow such cases to go unrecognized. Minot¹⁸ has discussed the existence of mild deficiency disorders in which, although a proper diet is fed, defective absorption or an abnormal gastro-intestinal function might result in mild symptoms. In the diabetic patient not only achlorhydria but also the existence of a dilatation and atony in the intestinal tract, especially of the colon as Dr L. B. Morrison has so often demonstrated as a result of the roentgenologic studies of patients, or of cholelithiasis, may contribute to a mild deficiency disorder expressing itself in mild anemia, neuritic paresthesias or more severe neuropathic states.

Chvostek¹⁹ regarded chronic pancreatitis as a distinct factor in producing anemia. He reported three cases in one of which there was diabetes, and discussed the literature with especial reference to hemochromatosis and cirrhosis of the liver and of the spleen. Conceivably, as a result of the interference with pancreatic function, a disturbance of the plasma lipoids might result in such concentration of hemolytic lipoids as to cause anemia. Another possibility dependent on pancreatic disease, which he considered, was that some hemolytic substance might be derived from the abnormal gastro-intestinal mucosa. However, the ordinary evidences of severe pancreatitis, such as fatty diarrhea, starch in the stools, and emaciation have not been noted in the cases here described.

TREATMENT

The results of treatment, by means of liver and insulin have been uniformly good in my patients. The causes of failure so far reported have been the advanced condition in which the treatment was begun,

the presence of severe complications or, in Wright's case, the development of polycythemia under treatment Tillgren²⁰ had two deaths, one from diabetic gangrene and one from tuberculosis. Varga²¹ reported good results consisting of improved appetite and strength in the treatment of pernicious anemia with insulin. Since the report of Blotner and Murphy²² of the effect of feeding liver on the blood sugar, it has been hoped that diabetes could be treated in this way. However, Bowen²³ reports a case of combined pernicious anemia and diabetes in which no benefit was observed from the use of liver in controlling the diabetes, and in my cases of combined pernicious anemia and diabetes I could not prove that the liver reduced the insulin requirement. In fact, patient 10 during three months' observation on a diet in which the carbohydrate was gradually increased from 145 to 165 Gm increased his insulin dose from 20 to 40 units. Patient 5, during three months' treatment in the hospital, received daily 300 Gm of liver, half the amount raw and half the amount cooked. In spite of the improvement in symptoms of the central nervous system, no reduction in insulin requirement or lowering of his average blood sugar level was noted. However, it must be admitted that careful studies of this point were not made. The diet which was prescribed during the period in which he gained steadily and which is typical for the other cases in this group, is given in table 5.

TABLE 5—Diet of Patient 5*

Egg 1	20% cream 180
Meat 60 Gm	Shredded Wheat ½
Liver 300 Gm	Grapefruit 200
5% vegetables 500	Orange 200 Gm
Unedas 2	Peach 165
Butter 5	Apple 165
	Liver extract 2 vials (Lilly)
Carbohydrate	133 Gm
Protein	99 Gm
Fat	78 Gm
Calories	1 630

* The patient was a man aged 57. March 1 1929. He weighed 131 pounds (59 kg). Insulin 10 units was given. The fasting blood sugar was 0.22 per cent.

In view of Muller's observations one cannot help but ask whether a low fat diet is proper in treating pernicious anemia and diabetes. Largely as the result of suggestions from Dr. George R. Minot, my patients have received diets planned to contain liberal amounts of vitamins. Thus, not only the vegetables, such as lettuce and carrots, and fruits, such as oranges, lemons, raisins and apricots, but also cod liver oil and yeast concentrate have been used.

The insulin dosage for the cases of combined diabetes and pernicious anemia in the Deaconess Hospital has varied from 5 units to a maximum of 42 units daily. No insulin reactions have occurred and no instance of insulin resistance has been observed.

SUMMARY AND CONCLUSIONS

1. A series of forty-eight cases of combined diabetes mellitus and pernicious anemia, including seven autopsies, was observed.

2. The symptoms of diabetes preceded the symptoms of anemia in the great majority of cases.

3. Factors predisposing to a more frequent combination of the two diseases are the greater duration of life

brought about by improved treatment of each disease and greater interest in diagnosis.

4. Achlorhydria, which is frequent in diabetes and becomes more frequent with increasing age, may be an etiologic factor. Gastric analysis and examination of the blood for evidences of anemia should be performed on all diabetic patients and particularly searched for in cases of long duration.

5. Treatment by means of insulin, liver or a potent substitute, and a diet rich in vitamins gives good results.

ANTIPOLIOMYELITIS HORSE SERUM

ITS PREPARATION AND USE*

MARCUS NEUSTAEDTER, M.D., PH.D.

Chief Visiting Neurologist, Neurological Hospital, Welfare Island
NEW YORK

In 1910, Flexner¹ reported an attempt to produce an immune horse serum against poliomyelitis as follows:

It has, for instance, been found that the horse does not readily respond even to large injections of filtrates carrying the active virus with the development of immunity principles within the blood. It is true that our experiments are restricted to a single horse for the present, the blood serum of which, after many months of treatment, had no restraining effect on the virus either in vitro or within the body.

It is a known fact that not every horse responds readily with the production of immunity substances alike to every kind of antigen, so that several horses must be tried. This one experiment, therefore, did not discourage me. Then, again, another method might lead to success when this failed.

With this view in mind I enlisted the cooperation of Dr. Banzhaf, one of the assistant directors of the Research Laboratories of the Department of Health of the City of New York, who henceforth collaborated with me in all this work and is equally entitled to all the credit or the blame.

In August, 1916, we² began to inject a horse with trypsinized filtrates of cord and brain suspension of children that died of poliomyelitis. After twenty injections, we decided to continue with subcutaneous injections of 5 per cent suspensions containing the live virus without any trypsin and this method we have pursued throughout our entire work for nearly thirteen years. Brains and cords of monkeys that were successfully infected with poliomyelitis were used whenever human material was unobtainable.

The serum of this horse protected one monkey completely from an intracerebral inoculation of 0.5 cc of a 5 per cent suspension of a very potent virus. This animal received nine daily injections of the serum, 3 cc intraspinally and 17 cc intramuscularly. Two monkeys were protected from intracerebral injections of a mixture of one part of virus suspension and two of the serum. The controls came down promptly with poliomyelitis and died. Their brain and cord presented the characteristic pathologic changes of the disease.

Thus we had good reason to believe that we had a horse serum that contained immunity substances sufficient to protect the animal by the restraining effect on the virus in vitro as well as in the body. By continued

injections we were able to obtain a serum from this horse that neutralized virus *in vitro* in the proportion of two parts of virus and one of serum. Encouraged by these results we continued our work during the following thirteen years by inoculating three more horses with equally good results.

In 1918, a year after the publication of our work, August Pettit³ reported our work and continued it along our lines with a sheep at first and then with a horse. He reported that his serum neutralized one part of virus with two parts of serum.

In 1928, Dr. Park was prevailed on to work on the problem. Our horse, which had been injected for ten months with virus of brain and cord that was inadvertently preserved in an acid glycerin and later through animal experimentation discovered to be avirulent, was turned over to Dr. Park who found that the horse had no neutralizing value at that time. With a known virulent virus then our method of treatment of the horse was mapped out by Banzhaf. By continuing the injections of our horse a very potent serum was obtained, Banzhaf having succeeded in concentrating it sufficiently to neutralize over 100 parts of the poliomyelitis virus *in vitro*. It is, of course impossible to say how high the potency of our previous serums was, for we had no means to go on with our experiments in a more extensive manner. During the thirteen years of our work we were not able to procure monkeys in sufficient numbers to work on the problem in a manner extensive enough to test out every possible phase.

Clinically, the most gratifying results should be obtained in the preparalytic stage of the disease. With the ordinary methods of diagnosis at present in vogue one cannot be even reasonably certain of a correct diagnosis at this stage, it is guesswork at best even during an epidemic. In sporadic cases it is certainly impossible to diagnose poliomyelitis in the preparalytic stage. At this point I want to reiterate that the complement fixation of the spinal fluid of frank or suspected cases of poliomyelitis with our antigen is the only available means at present that is helpful in the diagnosis. In 1917 we⁴ published the first results of our work on complement fixation with the specific antigen in acute poliomyelitis sufficiently gratifying to warrant the continuation of the work. It was done in collaboration with Miss M. A. Wilson of the research laboratories and has been sufficiently corroborated by other technicians since then.

The criterion of the efficacy of the serum, however, can be tested in frankly paralytic cases only, and this was amply demonstrated by the French clinicians and to some extent by us as well. Our experience is limited to six frankly paralytic cases in which we obtained most gratifying results—four of our own and two of Netter in Paris, to whom we sent 500 cc. of our serum six years ago. I regret to say that in spite of the positive experimental evidence in the last thirteen years at the research laboratories of the department of health of this city under the auspices of its director, Dr. Park, no opportunity was afforded us to test the value of the serum clinically. There certainly appeared from time to time cases of poliomyelitis in the Willard Parker Hospital and the serum was there always at their disposal. It is as harmless as ordinary horse serum or, for that matter, as any other antitoxin, so that no

untoward effect could possibly be anticipated from it. It certainly is deplorable that the pioneer clinical work was left to Europe.

Pettit⁵ reports the successful use of the serum clinically in twenty-five cases with frank paralysis, Netter⁶ in twenty-two cases, Etienne⁷ in several, and Minet and Porez⁸ in four. Parouneix⁹ relieved a bulbar paralysis and further on mentions a case of Stroup Beneck with a total paralysis of all four extremities and one of Debre with a bulbar paralysis as promptly ameliorated by the serum. Abroad it is used as Pettit serum.

A word may be said about the possibility of improving cases of frank paralysis. The pathologic changes characteristic of poliomyelitis in the acute stage consist chiefly of a reactionary inflammation of the cerebrospinal axis and in a small number of cases, of the peripheral nerves also. There is a perivascular infiltration of the meningeal, pial and parenchymatous vessels with mononuclears, polymorphonuclears, endothelial cells and plasma cells, together with a neuronophagocytosis. Edema is an early accompaniment. These changes may be slight and yet may produce extensive pareses. They may be regressive and the paralyses will disappear, as in some reported spontaneous recoveries, or they may become progressive and enhance degenerative changes of the nerve elements involved, producing permanent paralyses that defy all treatment. For this reason it is advisable to administer the serum in all cases, since it is clinically impossible to ascertain to what extent degenerative changes have set in. Of course, the earlier the serum is administered the better, and the ideal to be approached is to use it in the preparalytic stage, if and when a diagnosis can be made with any degree of certainty. Patients with a frank paralysis who still have fever should be treated. We know that some cases continue to improve even as late as up to two years.

As a further proof of the tenability of my theory may be cited a report of Netter⁹ on the use of human convalescent serum in frankly paralytic cases. In 1910 he used the serum in a case of the Landry type with complete success, beginning the treatment forty hours after the onset of the paralysis, again in 1913 he reported a case of the Landry type beginning treatment fifty hours after the onset of the paralysis and continuing without pause. He not only arrested the progress but also produced a complete disappearance of a paraplegia with retention. In 1914 he reported a case of bulbar paralysis with strabismus, a facial paralysis and hemiplegia, treated with the human serum with a resulting complete recovery. In a later communication he cited Zingher's nine cases in 1916, Macnamara's (Melbourne) three cases and Marinresco's bulbar cases with complete recovery. Interesting are Salamer's three cases, reported by Netter, in each of which the paralyses appeared in saccades successively some days apart. In these patients the serum was used six or eight days after the onset with success.

METHOD OF HORSE SERUM THERAPY

The immediate effect of the administration of the serum in the monkey is not closely analogous to that in man, particularly when injected intraspinally. The monkey apparently stands the serum well when it is

injected daily intraspinally and intramuscularly at the same time. In man, however, intraspinal injections invariably produce violent reactions, characterized by a rapid rise of temperature up to 104 or 106 F., and at times even convulsions and coma. Pettit and others report similar experiences. The intravenous and intramuscular routes are practically devoid of any unpleasant effects if properly checked and are just as effective. The safest method to forestall an anaphylactic reaction is to inject the patient with one-fourth grain (16 mg.) of morphine and one one-hundredth grain (0.6 mg.) of atropine sulphate, and after several minutes to inject a few minims of the serum subcutaneously. If after ten minutes no reaction appears, it is safe to proceed with the intravenous or intramuscular injection of the serum.

The dose of the native (unconcentrated) serum for adults is from 20 to 30 cc. every twenty-four hours or on alternate days, depending on the severity of the case, the dose for children is, of course, less according to age. In a very severe case I have given 20 cc. intravenously twice in twenty-four hours with gratifying results. The dose may be continued daily until the temperature drops to normal, or longer when necessary until ten injections have been given. A Herxheimer reaction is the indication of the limit of safety. The combination of an intravenous and an intramuscular injection is advisable in the first two or three days in particularly severe cases. The concentrated serum can be given in 5 cc. doses. Intramuscularly it produces a Herxheimer reaction after the third dose, it seems to be better tolerated intravenously. Since it is possible to go further clinically with the native serum before a Herxheimer reaction is apt to set in, I prefer this to the concentrated. In my experience and that of foreign investigators, the intravenous and intramuscular routes are devoid of unpleasant reactions and yield gratifying results, so that the intraspinal method has been abandoned.

At this point I want to report an interesting case of poliomyelitis treated with the serum, because it is rather the unusual type.

F. L., a boy, aged 16, developed fever, Aug. 20, 1928. The following day the throat became congested and he vomited several times. In addition there were headache and general malaise. The temperature which was not over 102 F., began to recede on the fourth day. Then weakness, pain and a tremor set in the right arm, so that he had to hold it in a sling. The tremor ceased after a few days but the arm grew constantly weaker and all the muscles of the right upper extremity and shoulder as well as of the scapula began to waste. He stated that he lost 15 pounds (6.8 Kg.) in two weeks.

November 3, when I first saw him, he presented the following symptoms. There was a fair degree of paresis in the entire upper right extremity and shoulder. He was unable to raise the arm or to resist passive motion to any appreciable extent, especially on flexion. All muscles of the right upper extremity, chest, shoulder and scapula were considerably atrophied and exhibited a partial reaction of degeneration. In spite of the fact that he still complained of pain, no tenderness could be elicited on pressure along the course of the peripheral nerves and the pin prick was felt equally well on the two sides. His temperature was then 100.2 F. by mouth. The pupils were rather sluggish to light but prompt to accommodation and in convergence. Otherwise he was neurologically normal.

Under usual precautions he received four daily intramuscular injections of 15 cc. of the native serum. The temperature became normal after the third dose. After the fourth dose the motor power of the forearm began to improve. The

following day he developed slight serum sickness, so no other serum treatment was instituted. The Herxheimer reaction was accompanied by a slight elevation of temperature, which promptly subsided under the influence of atropine.

Mild galvanism and massage three times weekly were then instituted and the boy continued to improve unremittently. The electrical response to faradic current was equal to that of the left arm. I discharged him as completely recovered in January 1929.

There is no doubt that the case was one of poliomyelitis involving not only the anterior horns of the cord but the posterior roots and ganglions as well and ran a subacute course with elevation of temperature. The prompt cessation of the continued wasting and decline of the motor power and the return of the temperature to normal after the treatment with the serum entitle me to assume that it was decidedly beneficial in this case.

SUMMARY AND CONCLUSIONS

The efficacy of our antipoliomyelitis horse serum and that of Pettit of Paris, who followed our method, was shown in more than sixty cases of frankly paralytic cases of poliomyelitis.

The earlier a case is diagnosed the better will be the result of the serum, if given early.

Cases presenting a chronic course with elevation of temperature should be afforded the benefit of the serum, which is as harmless as any other antitoxin. It can be standardized and obtained in large quantities and is always available.

27 East Ninety-Third Street

TRANSFUSION DONORS AS SOURCES OF IMMUNE SERUM FOR TREAT- MENT OF POLIOMYELITIS*

HAROLD K. FABER, M.D.
SAN FRANCISCO

Since human immune serum is the only available substance having a generally recognized specific therapeutic effect in poliomyelitis and since to be effective it must be used early in the disease, it is of the greatest importance that adequate supplies of serum, preferably of known neutralizing value, be on hand, or at least that potential donors of such serum be quickly available. Every one who has dealt with the problem in the presence of an epidemic is familiar with the considerable difficulties in satisfactorily solving it. The majority of cases of poliomyelitis occur in children, many of them so young that only small amounts of blood can be obtained from each even as late as two years after convalescence. Hence, as a rule where pools of convalescent serum are kept on hand they are made up of small samples from various sources. As the basis for such practice it is assumed that nearly all convalescents from poliomyelitis carry the specific viricidal substances in their serums.

In a recent contribution Shroughness, Harmon and Gordon have shown how far short of the truth such an assumption may be. In only four out of seven persons who had been attacked by the disease from six months to two years before the test did the serum neutralize poliomyelitis virus. Such observations are in

* From the Department of Pediatrics, Stanford University School of Medicine, and the University of California, San Francisco. Received for publication, June 1, 1929. (Revised manuscript received July 1, 1929.)

harmony with earlier ones of Netter and Levaditi,² Taylor,³ and others Aycock and Kramer⁴ in sixty tests with forty-one samples of convalescent serum, of which twenty-four were pooled lots from three or four individuals, had five failures. It is impossible to tell from their figures what proportion of convalescents were not immune, since most of the samples were pooled, but two of the individual samples and one pooled sample from three individuals failed to neutralize.

Shaughnessy and his associates confirmed and extended the earlier observations of Anderson and Frost,⁵ Peabody,⁶ Draper and Dochez⁷ and others that the serums of "normal" persons without history of previous attacks of poliomyelitis may contain immune bodies. They found that the serums of thirteen out of fifteen (87 per cent) such persons over 2 years of age were capable of neutralizing virus eleven of them in serum dilutions of 1:30 and two of them possibly in dilutions of 1:200. Eight out of nine persons 12 years of age or over gave positive neutralizing tests and the two highest titers in the entire series occurred in normal adults. Aycock and Kramer furnished the most exhaustive statistics on

of the fact that poliomyelitis occurs nearly every year in epidemic form somewhere or other. First, since the serum of convalescents from the disease does not always possess viricidal properties, it is highly desirable to have all samples tested for such properties before they are used therapeutically. This is by no means as difficult in practice as appears to be generally thought. A laboratory equipped to handle monkeys and having a stock of standard virus can make such tests. The expense, with monkeys at about \$15 apiece, is of course considerable, but it is not prohibitive. The testing might be considered a public responsibility and be carried out by the laboratories of state or municipal boards of health or, if done by private institutions, be paid for out of public funds. The cost can be reduced if donors capable of giving considerable amounts of blood repeatedly can be found, and this is the second point to be discussed.

It occurred to me that, since many normal adults possess viricidal substance in the blood, transfusion donors may in many cases prove to be suitable and convenient sources of therapeutic serum. If this is true, neutralization tests on listed donors could be made. Immunes detected, their blood obtained for stocks of

* Results of tests for viricidal antibodies on the serums of four normal human adults. A weighed quantity of glycerinated cord and medulla of a poliomyelitis monkey 211 was ground in the presence of carefully washed sterile sand for one hour in a Schultz-Banham grinder (Schultz E. W. and Banham F. D. Description of a New Mechanical Disintegrator. *Am. J. Pub. Health* 20:771 [July] 1930) and made up as a 5 per cent suspension in physiologic solution of sodium chloride. A portion of this suspension was lightly centrifuged for ten minutes and then filtered through coarse sterile filter paper. The filtrate was distributed in 1 cc amounts to a series of serologic tubes. To these tubes the various serums to be tested were added in 1 cc amounts giving a final serum dilution of 1:1. The mixtures were incubated at 37.5°C in a water bath for two hours and injected intracerebrally into *Macacus rhesus* monkeys each monkey receiving 1.5 cc of the serum-virus mixture. The injections were all made July 15, 1930.

† These serums were later retested with the same results indicated in the table.

the point. In forty-six normal individuals of urban residence, thirty-two, or 70 per cent, neutralized virus and of the thirty-four who were aged 5 years or older twenty-seven, or 86 per cent, neutralized. The neutralization of serums from individuals in rural communities was much lower. In a separate study⁷ of twenty-one adults from a Southern city, eighteen, or 86 per cent, neutralized virus.

Two practical applications which logically follow these experimental observations would appear to deserve the attention of the medical profession, in view

serum, and the problem of finding adequate, quickly available supplies for treatment would be solved. A list of donors for direct transfusion would be at hand if that procedure were desired in unusually severe cases.

To determine the practicability of the hypothesis blood samples from four of the donors on the list of Stanford University School of Medicine were obtained and tested for viricidal value by Dr. E. W. Schultz, professor of bacteriology, who determined that three of the four serums possessed protective value and the fourth, none.⁸ The details of his tests are shown in the accompanying table.

One of the donors belongs to group I, and two belong to group II of the Moss classification. In future tests we hope to find immune donors of the other two groups, and also to titrate the neutralizing values of the serum of our immune donors so as to be

7 Aycock W. L. and Kramer S. D. Immunity to Poliomyelitis in a Southern Population as Shown by the Neutralization Test. *J. Prev. Med.* 4:201 (May) 1930.

8 Since the manuscript of this report was submitted to THE JOURNAL Professor Schultz has tested the serums of nine more of our transfusion donors and found seven of them immune. Thus ten of thirteen (77 per cent) are immune which is in fairly close agreement with the other series cited in the text. One serum neutralized in 1:60 dilution. In the recent California epidemic our immune donors supplied more than 5 liters of blood for treatment, in a few cases by transfusion.

able to select for therapeutic purposes those having the highest concentration of antibodies

As the result of the tests made on these four persons three potential donors of antipoliomyelitis serum of established value were found who can on a moment's notice furnish sufficient blood or serum to treat a very considerable number of patients. This is an obvious gain over the present method of depending on pooled stocks or individual convalescents' blood of unknown value. It is highly probable that the antibody content of pooled serum is frequently lowered by the inclusion of samples of no value, and individual untested samples (or even pooled samples, as shown by Aycock and Kramer) may contain no antibodies at all.

The following suggestions are made:

1 It is advisable to test for viricidal properties those samples of human serum intended for the treatment of poliomyelitis. Pooled serums may have low or inadequate amounts of immune antibodies, owing to the inclusion of nonimmune serums and consequent dilution of the immune fractions. The tests, though expensive, are entirely practicable.

2 State or municipal boards of health might be charged with the duty of making such tests or of defraying the expenses when performed by such private agencies as properly equipped private research institutions.

3 Adult transfusion donors are frequently immune to poliomyelitis, and their blood, when tested and found to contain viricidal properties, forms an abundant and readily available source of serum for treatment. The testing of transfusion donors for such immune properties whenever and wherever possible is strongly urged.

4 The availability of transfusion donors for the treatment of poliomyelitis suggests the possibility of using large amounts of immune blood by direct transfusion in severe cases as a means of obtaining prompt and more thorough therapeutic action than is afforded by intramuscular or intrathecal injection.

THE EXTRACTION, DISTRIBUTION AND ACTION OF TESTICU- LAR HORMONES*

F. C. KOCH, PH.D.
CHICAGO

Although experimental and clinical evidence as to the effects of castration, as well as numerous experimental transplantation studies, conclusively prove that the testes possess one or more endocrine functions, nevertheless the biochemical evidence for the extraction of a postulated hormone from testis tissue was not definitely established until recently. To be sure numerous claims have been made from time to time, only to be unconfirmed later.

Brown-Sequard¹ is credited with the preparation of the first extract. He prepared crude water extracts from dog and guinea-pig testes and claimed most remarkable effects from the subcutaneous administration of them on himself. He felt much improved in general, with greater capacity for physical and mental work and less need for laxatives. The general impression was that the subcutaneous injection of the product would prove beneficial in the treatment of the aged and of persons with neurasthenia. Later the

product was improved and stabilized by the use of glycerin as a preservative and by autoclaving or filtering through a porcelain filter. Nevertheless the product remained an exceedingly crude preparation containing numerous tissue constituents in much lower concentrations than in the fresh tissue. The dilution introduced in the mode of preparation was always at least tenfold. In the light of present knowledge it is doubtful whether the Brown-Sequard preparation could have contained a sufficient amount of the one hormone now recognized as stimulating the secondary sex characters and accessory gonads to have influenced such elements in the clinical observations made by him and others. Brown-Sequard himself never stated that his product influenced the secondary sex characters but that probably two physiologic effects could be expected from his preparation: first, a prompt diuretic action and secondly, but later that of "activating nutrition." He also emphasized the possibility of suggestion or idiosyncrasy being factors in his case and expressed his desire to have other physicians confirm his observations. In general it seems necessary to conclude that such confirmations have been so few and the negative results so numerous that at present Brown-Sequard's assertions are not taken seriously. The best partial laboratory confirmations of his statements were given by Zoth² and by Pregl,³ who by means of ergographic records on themselves as well as on others found that the glycerin Brown-Sequard preparations did increase muscular efficiency and delayed the onset of muscular fatigue. Proper controls on glycerin were made, but similar extracts prepared from other tissues than testes were not tried. Zoth and Pregl used preparations supplied by a commercial laboratory. Dixon⁴ reported that saline extracts from fresh testis tissue cause a fall in blood pressure and a slight stimulating action on involuntary muscles. It is obvious that the Brown-Sequard preparations used were extremely crude and it is not at all unlikely that some of the effects observed were due to vasodilatants that could easily have been obtained from other tissues as well. A specific hormone action certainly was not demonstrated.

Among those who reported influencing secondary sex characters by extracts similar to the Brown-Sequard preparations are Ancel and Bourn⁵ and Walker.⁶ The former prevented atrophy of the penis and seminal vesicles in castrated guinea-pigs with subcutaneous injections every two days, while the latter caused comb and wattle growth in hens by the injection of saline extracts from cockerels' testicles. The doses employed by these observers are very small as compared with present practice for it is now found necessary to inject daily the equivalent of at least 50 Gm. of testis tissue to cause a measurable comb growth in five days in capons.

Poehl's spermine was the next product for which remarkable therapeutic values were claimed. Although first discovered by Leeuwenhoek⁷ in 1678 rediscovered by Vauquelin in 1791 and then studied in more detail by Schreiner⁸ and by Ladenburg and Abel⁹ it was not

until von Poehl¹¹ investigated it that its catalytic oxidative action was claimed, as a result of which it was introduced clinically. It is now known that spermine is widely distributed and that the claims as to its physiologic action have not been satisfactorily confirmed. Through the work of Rosenheim, Dudley and Starling¹² as well as the studies by Wrede,¹³ the structure of spermine is now known to be that of a symmetrical bis-aminopropylamine butane. Its synthesis demonstrates its formula to be $\text{NH}_2-(\text{CH}_2)_3-\text{NH}-(\text{CH}_2)_3-\text{NH}-(\text{CH}_2)_3-\text{NH}_2$. Spermine obviously does not fulfill the postulated characteristics as to distribution and physiologic action of a testis hormone.

Iscovesco¹⁴ studied the lipin fractions obtained from ovaries and testes and concluded that a certain fraction from the latter when injected in doses of 0.01 Gm per kilogram of body weight caused in the normal rabbit in from two to three months an hypertrophy of the testis and slightly higher weights for the kidney, thyroid and whole body as compared with controls while in man he observed "effects which could be interpreted as resulting from a similar stimulating action." He actually attempted to fractionate his material but his biologic basis for the detection of his potency is very unsatisfactory and unreliable.

Pezard¹⁵ was the first to use the capon as a test animal for the hormone affecting secondary sex characters and reported that when the equivalent of "one tenth of a cryptorchid hog testis" is injected twice weekly into an Orpington capon one observes a growth of comb, wattles and ear lobes as well as a more masculine behavior. As he did not describe his method of extraction he may have employed a suspension of testis tissue. His dosage also appears unusually low. The same is true of Ssentjurn,¹⁶ who reported that he retarded regression of comb size in capons by injection of the Locke's solution perfusates from bulls' testicles. He even states that by means of the Lichtgrun Manoiloff test one can determine the relative concentration of the active substance in the perfusate. This is extremely doubtful.

Korenchevsky and Carr¹⁷ reported that the injection of "testis emulsions" causes an increased nitrogen metabolism in "most dogs" and that an insulin-like action can be shown to be present in testis and kidney tissue extracts which lowers the nitrogen metabolism in thyroidectomized, normal and castrated rabbits. Their figures are by no means convincing.

The foregoing review of the work prior to 1926 on extracting the testicular hormone clearly shows that the experimenters either employed very crude modes of extraction or that the biologic response used was of extremely doubtful value. In most cases the experimenter not only attempted to interpret an exceedingly doubtful biologic response, but in addition he employed a crude product. The first report giving clear cut evidence of extracting and fractionating the hormone from testis tissue was given by L. C. McGee¹⁸ who repeatedly obtained a lipin fraction from bulls' testis

tissue which, when injected into brown Leghorn capons, produced marked growth of comb, wattles and ear lobes, and, when injected into the castrated guinea pig, prevented the usual atrophy of the seminal vesicles. Subsequently he, and Gallagher in collaboration with C. R. Moore and his students,¹⁹ showed that the same extracts previously standardized on the capon also correct the cytologic and other accessory gonadal changes observed in the castrated rat and guinea-pig. Independently Loewe and Voss,²⁰ using the regeneration of the seminal vesicle of the castrated mouse as a test, arrived at similar conclusions and also reported finding the same substance in adult male human urine. Subsequently Funk, Harrow and Lejwa²¹ also found the comb growth stimulating substance in urine and still later in testis tissue.²² The application of the mouse seminal vesicle regeneration test has also been independently carried out by Martins and Rocha e Silva.²³ These numerous confirmations, together with later reports by still others,²⁴ definitely establish a method for extracting from testis tissue at least one hormone which affects certain secondary sex characters in the capon and in the castrated mouse, rat and guinea pig.

EXTRACTION OF THE HORMONE

The method as devised by McGee, Gallagher and Koch¹⁸ is briefly as follows. The testes after being freed from epididymides and tunics, are finely hashed and extracted for three or four days at room temperature with from 3 to 4 volumes of 95 per cent alcohol. The alcoholic solution obtained is concentrated under diminished pressure until an aqueous emulsion or suspension of lipins is obtained. This is then repeatedly shaken with equal volumes of benzene and the combined benzene extracts again evaporated under diminished pressure. The resulting lipin mixture is next dissolved in acetone and cooled to 10° C. The clear acetone solution is separated from the inert precipitate and again evaporated under diminished pressure. The product thus obtained can be further purified by partition between hexane and various percentages of alcohol in water, resolution in ether, and shaking the ether solution with aqueous sodium bicarbonate, sodium hydroxide and acids. The final product can be made to be of an activity such that from 0.01 to 0.03 mg daily causes an appreciable comb growth in a capon in five days. One milligram of such an extract represents from 12 to 18 pounds of testis tissue. This low yield is not due to loss or destruction of a great amount of the substance in the process of purification but to the extremely low concentration of the hormone in testis tissue. To bring about a measurable comb growth response in five days in a brown Leghorn capon, the extract from 50 to 75 Gm of fresh tissue must be injected daily. It is because of this low concentration that the observations of earlier workers with amounts

equivalent to from a thousandth to a hundredth of our doses seem of doubtful value. The low yield has been a matter of considerable concern to this laboratory, but all attempts to improve it by reextraction or by acid alkaline or enzyme hydrolysis prior to extraction have not succeeded.

DISTRIBUTION OF THE TESTICULAR HORMONE

Every testis tissue thus far examined by this laboratory yields some activity. Hog and bull testes uniformly yield active extracts, but rams' testes vary considerably in their content, the yield usually being lower than from bull testes, and sometimes the results are negative. In the case of rams' testes the variation may be seasonal. Comparative studies on cattle testes indicate that the embryonic and calf tissues are richest in hormone content, with adult bulls somewhat less and old bulls least potent. No other bull tissue examined except epididymides yielded active preparations in the hands of Gallagher. Cows' ovaries also gave negative results in his hands.

As previously stated, Loewe and Voss and Funk, Harrow and Lejwa reported finding the hormone in adult human male urine. This laboratory has confirmed these observations. Funk, Harrow and Lejwa reported the daily rate of excretion as distinctly higher in mature than in old men. Wornick and Koch² find that the hormone is either absent or present in thus far undetectable amounts in the urine from boys under 10 years or from young calves under 2 years of age, while in the urines from adolescent boys or mature men the amount present is appreciable. It is present in approximately one-half the concentration found in bulls' testes. We have also found the comb growth stimulating hormone in the urine from mature (pregnant or nonpregnant) women in concentrations of the same order as in men's urine. The negative observations on boys' and calves' urine may possibly be interpreted as indicating that the hormone is not secreted as rapidly before puberty as later. It certainly is present in the embryonic and in the prepubertal testes but it does not appear to escape into the urine before puberty. The source of the hormone in women's urine remains to be determined. At the present writing our quantitative studies indicate that the normal adult man or woman is excreting an amount of hormone every twenty-four hours equivalent to approximately one pound of bulls' testis tissue. If these observations are correct and the source of the hormone in the case of the male is the testes only, it must be concluded that this tissue is elaborating the hormone at a relatively rapid rate. The hormone has also been found in blood²⁸ and in the male blossoms of the pussy willow.²⁹

MODE OF ADMINISTRATION OF THE HORMONE

In the experimental studies of this laboratory as well as in our cooperative investigations with the Whitman Laboratory and with Professor Moore in the department of zoology we have obtained the most uniform and successful responses from the subcutaneous or intramuscular injection of our preparations dissolved in olive oil. The same preparations when given by mouth with or without olive oil saponin or proteins led to irregular results even though ten times the injection dose was used. The material appears to be poorly

absorbed from the intestinal tract because an appreciable amount is found in the feces after such a feeding experiment.

CONCLUSIONS

Active preparations of a testis hormone have been concentrated to a fair degree of purity. The product acts best when injected subcutaneously or intramuscularly; the dose for action by mouth is at least ten times as high. The physiologic actions observed thus far are the effects on the secondary sex characters in the capon and the accessory gonads in the mouse, rat and guinea-pig. No claim can be made that the product also affects behavior, metabolism or "vigor." Whether these responses are due to other hormones or whether larger doses over longer periods of treatment are involved remains to be determined.

In the light of these results on animals, it is reasonable to expect that similar generalizations will hold with reference to man. Thus far there is no indication that this product can be of any value in restoring vigor to the aged or neurosthenic. However, if there is an indication for its use and if the dosage in man is comparable to that found in the capon, the daily injection for a 150 pound man would have to be an amount equivalent to at least 5 pounds of bulls' testes tissue or 2 gillons of normal male urine. If taken by mouth, the dose presumably would have to be much greater. These deductions, based on animal experimentation, indicate the probable fallacy of prescribing testis preparations to man. It must be recalled that most of the proprietary preparations now on the market are to be taken by mouth and that they simply are made up of the desiccated and defatted ram or bull testicles. In the defatting process, no doubt a considerable part of the trace of hormone originally present is removed and discarded. The recent report from this laboratory on a well known proprietary product confirms these statements.³⁰

ETHER HYPERGLYCEMIA

WITH SPECIAL REFERENCE TO HEPATIC DISEASES

ABRAHAM CANTAROW MD

And

A M GEHRET, M D

PHILADELPHIA

The occurrence of hyperglycemia during and following ether anesthesia is well known and is one of the physiologic phenomena associated with that state. It is one of the striking manifestations of the effect of ether on carbohydrate metabolism. Mekic and Miller¹ reported elevations of blood sugar following ether anesthesia of varying duration; the degree of elevation varied from 27 mg per hundred cubic centimeters in 30 minutes to 47 mg in 110 minutes, a rise of as much as 62 mg being noted in some patients after 60 minutes. The amount of increase bore no relation to the nature of the operative procedure, although it was greater in laparotomies than in extra-abdominal operations. Similar observations have been made by Mackay,² Ross and Davis, and many others, values as

[illegible]

high as 400 mg per hundred cubic centimeters having been observed in prolonged anesthesia in individuals with normal carbohydrate metabolism.

There are, in the main, two theories that have been advanced in explanation of ether hyperglycemia. Ross and Davis⁴ believe it to be due to depression of the internal secretory function of the pancreas (hypo-insulinism), a temporary disturbance analogous to diabetes mellitus. The similarity to diabetes extends also to disturbances of fat metabolism and acid-base equilibrium. Blood⁵ demonstrated an associated hypemia and acidosis, the ketonuria that follows ether anesthesia is a matter of common knowledge. Mahler⁶ reported a progressive rise in plasma cholesterol, roughly proportional to the quantity of ether administered. It was found that both hyperglycemia and hypercholesterolemia could be prevented by the administration of 10 units of insulin two hours prior to the induction of anesthesia.

The belief in pancreatic depression as the cause of ether hyperglycemia is not generally accepted. It is more probable that the rise in blood sugar is the result of increased hepatic glycogenolysis due either to the direct action of the anesthetic or to the increased hydrogen ion concentration associated with ether anesthesia. Investigations of phosphate metabolism are of great importance in this connection. Bolliger⁶ found that in dogs the serum inorganic phosphate concentration dropped from 4.0 to 2.6 mg per hundred cubic centimeters at the end of one hour of anesthesia and was 1.0 mg one hour after the anesthetic had been discontinued. This observation is identical with the investigations made following the administration of dextrose, epinephrine or insulin, and appears to be due to the increased utilization of dextrose induced by those agents. Such changes would suggest that anesthesia hyperglycemia, as in the case of epinephrine hyperglycemia, is dependent on increased hepatic glycogenolysis rather than on hypo-insulinism.

Potter⁷ found the inorganic phosphate of the serum to be increased in five of seven patients during anesthesia, and Stehle and Bourne⁸ making similar observations, suggest that the diminished alkali reserve and increased acidity may be due to a discharge of phosphoric acid from the muscles. Haldane, Wigglesworth and Woodrow⁹ showed that the rise which may occur in serum phosphate is probably due to excessive muscular exercise and pure asphyxia and is not related to alteration in carbohydrate metabolism. According to Bolliger,⁶ the drop in serum phosphate that normally occurs is not observed in depancreatized dogs, another indication of the importance of proper pancreatic function in the production of this phenomenon. By direct methods, a reduction in the glycogen content of the liver following ether anesthesia has been demonstrated by Macleod and Pearce¹⁰ and Rosenthal and Bourne¹¹ found that hepatic function was diminished after anes-

thesia. In view of these and similar observations, it appears likely that the hyperglycemia of ether anesthesia is a result of the liberation of dextrose from glycogen stored in the liver.

The appreciation of this phenomenon is of great practical importance in connection with the preoperative and operative management of patients with obvious or presumptive disturbance of hepatic function. Injury to the liver, whether caused by hepatic poisons, infection or extrahepatic obstruction with biliary stasis, is associated with a diminution in the ability of the liver to store glycogen and with a corresponding decrease in its glycogen content. This has been demonstrated in several ways by Markowitz,¹² Olmstead and Coulthard¹³ Brill and Fitz-Hugh,¹⁴ Kugelmann¹⁵ and Ravdin.¹⁶ Conversely the ability of the liver to withstand injury is to a certain degree dependent on its glycogen content. This has been demonstrated experimentally by Davis and Whipple¹⁷ Umber¹⁸ and Ravdin.¹⁶ It is evident therefore that the effect of ether, which depletes the hepatic glycogen reserve, on a liver already poor in glycogen, may be productive of serious consequences.

PRESENT INVESTIGATION

The present study consists of the determination of the venous blood sugar concentration at brief intervals during operation, under ether anesthesia, on eight

Venous Blood Sugar at Brief Intervals During Anesthesia with Rise per Ounce of Ether Administered in Each Case

Case	Condition	Icterus Index	Blood Sugar Mg Minutes of Anesthesia							Rise per Ounce

iliary tract A point of striking interest and significance is the finding that in the jaundiced patients the rise in blood sugar per ounce of ether administered was 07, 47 and 39 mg, respectively, with an average rise of 29 mg per hundred cubic centimeters per ounce, whereas in the patients with latent or no icterus the rise was 90, 50, 84, 83 and 83 mg, respectively, the average rise being 76 mg per hundred cubic centimeters per ounce of ether. The average rise in the three patients without any biliary tract disease was 70 mg per hundred cubic centimeters per ounce of ether administered.

All the patients in this series made good postoperative recoveries with the exception of patient 1, who died eighteen hours after operation, the autopsy revealing extensive acute diffuse necrosis of the liver, no evidence of which had been noted at operation. From the standpoint of studies of hepatic function prior to operation, this patient differed in no respect from the others with frank icterus. Unfortunately, the epinephrine test was not performed. This might have revealed the deficient glycogen reserve of the liver in case 1, for, as is noted in the table, the blood sugar concentration remained practically unchanged during the period of anesthesia. All patients with biliary tract disease received the same preoperative treatment, including a diet high in carbohydrate with supplementary dextrose therapy. Their general condition was good during operation. The blood sugar level appeared to bear no relation to the nature of the surgical procedure or to the manipulation of individual organs during the course of the operation.

COMMENT

These observations emphasize the importance of the glycogen content of the liver in determining the operative risk in patients with hepatic disease. It is evident that the glycogenic function of the liver is impaired in patients with jaundice, even though the commonly employed tests of the carbohydrate metabolic function of the liver fail to reveal any significant disturbance. The fatal result in one case of this series illustrates the extreme difficulty of determining, preoperatively, the extent of hepatic insufficiency in this respect. So far as could be determined, this case differed in no essential from two others with higher grades of bilirubinemia, however, the failure of the blood sugar to rise under the influence of ether is sufficient indication of the fact that the hepatic glycogen content was extremely low and foreshadowed the eventual and inevitable outcome.

Although the individuals with biliary tract disease without frank jaundice exhibited a hyperglycemic response equal to that of patients without hepatic damage, it must be recalled that they received careful preoperative treatment designed to decrease biliary stasis, combat hepatic toxemia and increase the storage of glycogen in the liver. The fact cannot be too firmly stressed that all patients with disease of the biliary passages must be regarded as having some degree of hepatic injury. Because of the relatively great functional reserve and enormous regenerative capacity of the liver, this can rarely be demonstrated until it becomes advanced. However, even in the absence of jaundice, the added insult of ether anesthesia may be depleting an already diminished glycogen reserve, result in a stormy convalescence or a fatal issue. It is essential therefore that, so far as is possible, every effort be made to ensure an adequate hepatic glycogen content before operation on such patients.

SUMMARY AND CONCLUSIONS

The hyperglycemia associated with ether anesthesia is apparently due to increased hepatic glycogenolysis.

The average rise in blood sugar per ounce of ether administered was 29 mg per hundred cubic centimeters in a series of patients with frank icterus as compared with 76 mg in a series of patients with biliary tract disease without jaundice. Prior to operation, all had received a diet high in carbohydrate with supplementary dextrose therapy.

One patient, receiving 14 ounces of ether, failed to show any appreciable rise in blood sugar (07 mg per hundred cubic centimeters per ounce of ether) and died eighteen hours after operation. Autopsy revealed extensive acute diffuse necrosis of the liver which had not been present at the time of operation. Preoperative studies of liver function in this patient did not differ in any essential from those in the other jaundiced patients who exhibited definite although subnormal hyperglycemic responses and who made uneventful recoveries.

All patients with biliary tract disease should be regarded as having hepatic damage whether or not evidence of hepatic insufficiency is demonstrable.

Clinical Notes, Suggestions and New Instruments

TULAREMIA FROM THE FOX SQUIRREL REPORT OF CASE

TOM KIRKWOOD, M.D., LAWRENCEVILLE, ILL.

As an evidence of the increasing distribution of *Bacterium tularensis* infection in animals, I am reporting a new animal host—the fox squirrel. According to a personal communication from Dr. Edward Francis, the case to be reported is the first traceable to that source.

Mrs. J. K., aged 28, a farmer's wife, whose past history and general examination were negative, skinned and dressed a fox squirrel, Aug. 18, 1929. She did not handle or come in contact with any other game on that date. There had been no other possible chance for exposure during the preceding month. She had not been bitten by any insect. She was in excellent health Aug. 18, and no signs of infection appeared until August 20, when she had a severe chill accompanied by head ache, brackache and nausea. This chill was followed by an illness that lasted for four weeks. During this time she had chills, sweats and severe headaches, she lost several pounds and was left in an exhausted condition. On the third day of the infection she noticed that the glands under the right arm were enlarging and she soon had much pain and tenderness in that region. A day or so later she discovered a small papule on the dorsum of the distal phalanx of the third finger of the right hand. As the disease progressed this papule ulcerated and showed all the characteristics usually found in the initial lesion of the ulceroglandular type of tularemia.

The patient was certain that she had "blood poisoning" when I first examined her, August 31. She had consulted another physician who was well acquainted with the symptoms of tularemia and who, suspecting that disease, had sent a specimen of blood to the state laboratory for the usual agglutination test. The report on this specimen was negative. As all the typical clinical signs associated with tularemia were present when I first examined this woman, another specimen of blood was sent to the laboratory. This sample, which was taken on the eleventh day of the disease, was also negative. Another specimen submitted on the seventeenth day showed a positive agglutination for *B. tularensis* but the report from the state laboratory, dated of September 9, did not give the titer. A blood specimen was next sent to the Hygienic Laboratory of the U. S. Public Health Service, Washington, D. C. The report from there

dated September 30 showed a positive agglutination for *B. tularensis* in a dilution on 1:280, confirming the report from the state laboratory.

Dr. Edward Francis in the personal communication already referred to, states that this is the second case that has come to his attention of tularemia traceable to a 'tree' squirrel. The first was contracted from a black squirrel in Kansas, in the latter part of November 1928. These cases show conclusively that the tree squirrels must be considered as one of the possible sources of *B. tularensis* infection. The fox squirrel is found in large numbers throughout various parts of the United States and from the standpoint of the hunter of small game, is one of the important game animals. The possibility of *B. tularensis* infection in those who kill and dress these animals must therefore be remembered.

A CASE OF LEIOMYOSARCOMA OF THE STOMACH*

LEON SCHIFF, M.D. AND MARGARET FOLLGER, M.D.

Assistant Professor of Medicine and Assistant in Medicine, respectively, University of Cincinnati College of Medicine

CINCINNATI

A white man aged 50, a truck driver, was admitted to the medical service of the Cincinnati General Hospital March 26, 1930, complaining of chills and fever of five days duration. The chills had been occurring daily and were followed by profuse sweating. After the first rigor he experienced a severe pain in the left epigastrium. He felt a swelling there which had remained unchanged in size.

There had been no previous abdominal pain and no digestive disturbances other than occasional flatulence and eructation of sour material. The bowels were usually constipated. A penile lesion had been present twenty-five years before which was thought to be a chancre. When 10 years old he had chills and fever, which disappeared after the administration of quinine. He had received numerous intramuscular injections in the hips.

The patient was somewhat undernourished but did not appear acutely ill. There was a subicteric tint to the skin and sclerae. The pupils were unequal, were irregular and reacted sluggishly to light. The fundi were normal. There was no generalized lymphadenopathy. The heart and lungs were normal. The blood pressure was 98 systolic and 68 diastolic. There was some fullness in the left hypochondrium. A firm mass presenting a distinct edge and descending freely on inspiration was felt to extend four fingerbreadths below the left costal margin in the midclavicular line. The mass was somewhat tender and smooth save for a slight irregularity near its edge. It was thought to be an enlarged spleen. There was neither ascites nor detectable enlargement of the liver. The extremities and reflexes were normal.

A blood count showed 20,000 white cells with 89 per cent neutrophils, 6 per cent lymphocytes, 4 per cent large mononuclear and transitional cells and 1 per cent eosinophils. Red cells numbered 4,500,000 per cubic millimeter. The hemoglobin was 55 per cent (Dare). Some achromia was present, no malarial parasites were found. The urine was normal save for the presence of 1+ albumin. The blood Wassermann test was negative. Blood sugar was 105 mg, urea 13 mg, and uric acid 17 mg per hundred cubic centimeters. The serum bilirubin was not increased, 0.2 mg per hundred cubic centimeters induct (van den Bergh technique). The erythrocytic fragility was normal. The platelets numbered approximately 490,000 per cubic millimeter, reticulocytes 2 per cent.

Shortly after admission, the patient began to complain of sharp epigastric pain, nausea and vomiting. The temperature, which on admission was normal, rose to 103.2 F with a corresponding increase in the pulse rate.

A fluoroscopic examination of the gastrointestinal tract, much to our surprise, revealed the presence of a large irregular niche on the lesser curvature of the stomach, several inches above the pylorus, which Dr. H. G. Reineke interpreted as a subacutely perforating gastric ulcer and which he felt was related to the mass thought to be the spleen.

Exploratory laparotomy was performed by Dr. Malcolm Cook. A tumor mass was felt on the posterior wall of the stomach extending upward to the lesser curvature. As the lesser peritoneal sac was bulging, it seemed probable that perforation had occurred. Incision through the gastrosplenic omentum revealed a large amount of foul smelling pus which was drained. The spleen was found to be normal in size and consistency. Following the operation the patient's course was steadily downward, and death occurred four days later.

At necropsy, Dr. J. N. Patterson found several small ragged sinuses on the lower posterior wall of the stomach communicating with the lesser peritoneal sac, which contained a walled off abscess. The sinuses were traced further and found to lead into an irregular shaped cavity, resulting from necrosis of the posterior wall of the stomach. Along the lesser curvature near the pylorus, the gastric mucosa was thrown up into a large irregular mass in the center of which there was an ulcer 7 mm in diameter which communicated with the cavity in the posterior wall. The edges of the ulcer were found to consist of tumor tissue. There was an area of recent ulceration in the mucosa of the midportion of the posterior wall, which also communicated with the cavity. Microscopic examination of the tumor tissue proved it to be leiomyosarcoma involving the various layers of the stomach wall. A metastatic nodule approximately 5 cm in diameter was present on the anterior superior surface of the left lobe of the liver and a second 1 cm in diameter in the lower lobe of the right lung posteriorly.

This case is of interest because (1) leiomyosarcoma of the stomach is relatively infrequent, (2) the symptoms were apparently due to an abscess in the lesser peritoneal sac, (3) the mass present simulated an enlarged spleen and (4) the gastric lesion produced a niche roentgenologically which according to Alexander Moore, is very unusual with leiomyoma.

REFERRED PAIN IN A TRAUMATIC INTESTINAL RUPTURE

RICHARD JOSEPH WHITE, M.D., FORT WORTH, TEXAS

During the past ten years the incidence of jejunal ulcer following gastro-enterostomy has been studied intensively. Von Haberer in Europe and Lewisohn in America have been led by its alleged frequency to advocate extensive gastric resections for duodenal ulcer. This discussion has incidentally diffused much information about the symptoms of jejunal ulcer. It causes pain regularly below and to the left of the umbilicus. In view of this well established clinical observation, the following case is of interest.

E. L. N., a boy, aged 6 years, was brought Sept. 3, 1930, to the Cook Memorial Hospital. He had been knocked down and run over by a light automobile. He complained at once and continuously of pain in his stomach. Physical examination showed extensive abrasions and contusions. Lesions were scattered over the arms and legs, and there was a severe bruise about the right eye with a subconjunctival hemorrhage. There was no bleeding from the ears or mouth. The boy was apparently perfectly clear mentally. The lungs were clear and the heart sounds were normal. The pulse was 120 but of good quality. His color was good and his skin dry. The temperature was 100 F. There was no evidence of any fracture or dislocation. The boy was extremely restless, turning from his back to his abdomen and back again. He repeatedly placed his finger just below and to the outer side of the navel and said that he hurt only there. There was a band of contusion extending from the lower ribs on the left side downward and obliquely across the abdomen. The abdomen showed little rigidity. The liver dullness was not obliterated. There was no shifting dullness. Nothing was made out by rectal examination. The urine was clear, except for an occasional red cell and a few white cells. The red blood cells numbered 4,600,000, the hemoglobin was 75 per cent, the white blood cells numbered 19,800, with 68 per cent polymorphonuclears. Four hours later the hemoglobin was still 75 per cent. A flat plate of the abdomen showed no air above the liver.

The boy was in only moderate shock and though he could easily have suffered a severe intra-abdominal injury, the only complaint or physical sign that he had was a sharply localized

* From the Department of Internal Medicine, University of Cincinnati College of Medicine and the Medical Service, Cincinnati General Hospital.

pain just to the left and below the umbilicus. This is so frequent in jejunal ulcers that in upper intestinal injury came to mind. He was given no opiates and nothing by mouth and was examined hourly. He continued to point to the same spot as the site of pain. Four hours after the injury he vomited. Six hours after the accident his temperature was 102 and his pulse 130. He was mildly delirious and showed a slight abdominal rigidity. It was decided to open the abdomen. With procaine hydrochloride used locally, a small incision was made just to the left of the navel. A little thin clear yellowish fluid welled out. It was odorless and no fat necrosis or peritoneal irritation was made out. The patient was given ether and the incision lengthened. Considerable quantities of fluid issued from the wound, evidently containing some bile. The liver felt normal, the stomach, as far as could be seen, was not injured. As I reached toward the spleen, a gush of fluid came out and a few gas bubbles rose through it. The spleen felt normal. When the transverse colon was lifted up, the source of the trouble was obvious. At the beginning of the jejunum and extending up into the fossa of Treitz was a slightly oblique rent through the intestine, 1 inch long. The adjacent mesocolon and intestine for 2 inches about the tear were covered with thick fibrin. The hole was closed with two layers of chromic catgut. A smear of the free fluid showed no organisms. The abdomen was closed without drainage. The child's condition seemed bad at the close of the operation. The next morning he was greatly improved and had a rapid convalescence, marred only by a low grade infection in the abdominal fat.

It is interesting that a tear in the jejunum in the segment subject to ulceration following gastroenterostomy should have so accurately and conspicuously reproduced the referred pain of jejunal ulcer.

ACUTE TOXIC NEPHRITIS COMPLICATING ACUTE OBSTRUCTION OF THE SMALL INTESTINE

N I FOX, M.D., F. J. MANTEL, M.D., AND J. I. RABENS, M.D.
CHICAGO

S. B., a Negro, aged 24, was admitted, April 14, 1930, to the surgical services of the Cook County Hospital, Chicago, because of a swelling in the right inguinal region, vomiting, and severe abdominal cramps for the past twenty-four hours.

The patient stated that he had had a right inguinal hernia for the past two years. The day before, about 2 p. m. he suddenly developed a sharp, colicky pain in the right inguinal region. An hour later he noticed a round, hard and tender mass in the same area. The pain was followed soon by nausea and vomiting, the vomitus consisting of food material and mucus. About 3 o'clock the pain had spread over the entire abdomen and was especially marked around the umbilicus.

He vomited again at 5 and at 6 a considerable amount of grayish material. He tried to go to sleep but was awakened again by the pain. He took a cathartic but had no results. He suffered pain all night and could not sleep. At 8 a. m. he vomited again, the vomitus this time consisted of thin, brownish, foul smelling material. The pain in the inguinal region was getting worse. He called a physician, who advised him to go to the hospital. His past history was negative except for yellow fever at 12 and mumps three years before admission. The family history was negative.

The patient was well developed and well nourished. His temperature was 97 F, respiration, 22, pulse, 88, blood pressure, 160 systolic and 106 diastolic.

Physical observations were essentially negative except for the right inguinal region. Here a hard round and tender mass about the size of a large walnut was noticed. This mass increased in size and transmitted a definite impulse to the hand on coughing. The mass was reduced after a little manipulation. This resulted in relief from pain.

Urinalysis revealed a dark amber fluid, with a specific gravity of 1.036, albumin 4 plus, sugar and acetone 0. Many granular and hyaline casts were found in an uncentrifuged specimen.

On account of the hypertension, vomiting and the condition of the urine, an acute nephritis with impending uraemia was

considered and the patient was transferred the same day to our medical service for observation.

April 15 we saw the patient and found him quite comfortable, not acutely ill. The vomiting did not recur. The pain in the right inguinal region and abdomen had disappeared since the reduction of the hernia. The blood pressure had come down to 140/78. The urine still showed albumin 2 plus with many hyaline and granular casts in a centrifuged specimen.

The further progress of the case was uneventful. The albumin and casts diminished from day to day, so that on April 19 the urine was free from albumin and casts. The blood pressure remained normal. The blood indican test was negative. The report of the chemical examination of the blood having been misplaced we cannot give exact figures.

A Mosenthal test, April 19, gave concentration, 1.006-1.018 and 1680 cc. secreted from 10 a. m. to 8 p. m.

A phenolsulphonphthalein test, April 22, gave first hour 15, second hour 20, total 35.

The patient was transferred back to the surgery, where a herniotomy was performed, April 28. He was discharged, May 7, 1930. His renal function throughout convalescence was normal.

COMMENT

For some time it was known that in certain cases of acute obstruction of the small intestine there is often present severe renal injury which may be the cause of death. McQuarrie and Whipple¹ in experimental study of intestinal obstruction in dogs proved conclusively that the renal function was definitely impaired. They found a decreased elimination of phenolsulphonphthalein and chlorides in the urine with increased concentration of urea and nonprotein nitrogen and pointed out the possible clinical importance of these observations.

Tucker² has called attention to the renal factor in the toxemia and death following gastroenterostomy. He believed uraemia to be the probable cause of death. In four of his cases necropsy revealed the grafting of an acute process on a previously existing chronic nephritis.

Tilston and Comfort³ have shown a marked increase in total nonprotein nitrogen and urea in the blood in cases of acute intestinal obstruction.

Brown, Lusterman, Hartman and Rowntree⁴ have shown that severe renal injury exists in many cases of duodenal and pyloric obstruction. This toxic injury to the kidneys is of grave consequence and is characterized by albuminuria and cylindruria, marked functional impairment of the kidneys associated with marked increase of total nonprotein nitrogen of creatinine and urea in the blood, and a definite decrease of phenolsulphonphthalein excretion, a clinical syndrome due in part at least to renal insufficiency, and a well defined pathologic picture of toxic nephritis.

We can interpret our case, then, as follows:

A loop of the small intestine was caught in the inguinal ring producing a strangulated hernia and intestinal obstruction. Absorption of toxins from the obstructed intestine resulted in an acute toxic nephritis as manifested by the sudden increase in blood pressure, albuminuria and casts. Reduction of the hernia restored the function of the small intestine. The acute symptoms such as hypertension and vomiting subsided, the urinary symptoms subsiding more slowly but eventually clearing up. The phenolsulphonphthalein output remained below normal a longer period.

This case is interesting because of the rapid development of toxic nephritis in a case of acute intestinal obstruction of less than twenty-four hours duration and just as rapid abatement of symptoms with the disappearance of the obstruction. The danger of kidney damage must be considered in hernias in which loops of the small intestine are involved.

A CONFIRMATORY PHYSICAL SIGN IN ASCITES

J THORNWELL WITHERSPOO MD NEW YORK

In cases of ascites when one side of the abdomen is tapped with the finger and the other side is auscultated, two sounds similar in timing to the normal heart sounds have been observed. The first sound is caused by the sound wave being transmitted through the fluid; the second is the result of the fluid wave crossing the abdomen and striking against the auscultated side. These two sounds are heard more clearly in thin, tense abdomens as opposed to flat soft flabby ones and are best heard at the level of the fluid and intestine as demonstrated by an experiment with a closed rubber bag partially filled with air and water. There seems to be no reference to this auscultatory sign in cases of ascites in any of the standard textbooks on physical diagnosis.

It is stated by several of the German writers that when fluid is injected into the abdomen of an adult cadaver, 1500 cc is necessary before any of the usual physical signs of ascites appear, such as distended abdomen, shifting dullness, and the fluid wave. These signs and the auscultatory sign were present in eighteen cases of ascites examined and confirmed by abdominal aspiration operation, or autopsy. The auscultatory sign could not be demonstrated in any cases in which these signs were absent nor was it noted in abdomens markedly distended with gas. However it was clearly heard in one case of a large ovarian cyst which was later removed at operation.

This observation is offered here only as an additional confirmatory sign in the detection and diagnosis of ascites.

St Luke's Hospital

TRAUMATIC ULNAR NEURITIS DUE TO STRAPPING OF THE ELBOW AND THE FOREARM TO THE OPERATING TABLE

L S GURDJIAN MD DETROIT

The ulnar nerve traversing the epicondylar groove of the humerus in a subcutaneous position is apt to be injured through changes either within itself or in the surrounding tissues. Scar tissue formation in the groove caused by bruises and small hemorrhages may compress this structure and thus irritate it. When one considers the fact that the ulnar nerve with each flexion-extension movement at the elbow moves half an inch or more, one realizes the ease with which changes in the groove through which it traverses may irritate and alter its functions. In the next few paragraphs I shall describe the case of a young man, aged 24, who was taken to the operating room for herniorrhaphy. The upper extremities were strapped to the table in the usual manner. Soon after the reaction from the anesthetic he noticed a peculiar feeling of numbness in the little and ring fingers of the right hand.

I saw the patient ten months after the operation. The feeling of numbness in the ulnar distribution of the hand had persisted along with progressive weakening of the grip to the extent that he was unable to use the hand to advantage in his vocation of plumbing.

Examination showed definite hypesthesia in the ulnar distribution of the hand, inability to approximate the little finger and the thumb, and marked atrophy of the adductor pollicis and the interosseous muscles. The rest of the neurologic examination was essentially irrelevant.

A diagnosis of traumatic ulnar neuritis was made, and the patient was advised to have the operation of ulnar transposition and neurolysis, if necessary. This was performed. The ulnar nerve was taken out of the epicondylar groove and transposed to the anterior aspect of the elbow. Adhesions were noted between the nerve and the surrounding tissues. Neurolysis was not found necessary. A few days after the operation the numbness in the ulnar distribution disappeared. Three months later the adductor pollicis was about the same size as its fellow on the opposite side. The grip was practically normal.

COMMENT

This case illustrates an ulnar neuritis caused by strapping the elbow and the forearm to the operating table. It is possible that during the administration of the anesthetic and the period

of excitement he bruised the inner aspect of the right elbow and the walls of the epicondylar groove, followed by scar tissue formation. With the narrowing of the ulnar canal the nerve became chronically irritated through compression and adhesions. This is substantiated by the operative observations already described and by the fact that the patient recovered complete function soon after the nerve was transposed from its normal bed.

It is not within the limits of this case report to discuss at length the causes, clinical manifestations and operative treatment of traumatic ulnar neuritis. Several excellent papers have been written on the subject.¹ Suffice it to say that it is important to recognize such lesions as early as possible and after a period of waiting if the function does not return to perform the operation of ulnar transposition and neurolysis, if necessary.

Special Article

THE INDISPENSABLE USES OF NARCOTICS

IN THE PRACTICE OF MEDICINE*

FREDERICK TICE, MD

CHICAGO

As a preliminary to the therapeutic employment of narcotics it is advisable or necessary to consider what is understood by the term narcotics and how they produce their beneficial effect. There is no generally accepted definition or classification of the narcotic drugs, except, perhaps, that they are included in a group producing varying effects on the nervous system. In this comparatively large group are found not only narcotics but also hypnotics, soporifics, anesthetics, analgesics, antispasmodics and several other subgroups, more or less closely related in several respects but with some distinguishing characteristic.

The physiologic effect of opium and its derivatives depends in part on the particular preparation that is employed, as well as on the amount of the drug. In general terms it may be said that small amounts produce an exciting effect while in larger doses there is an analgesic action and in sufficient dosage hypnosis, coma and even paralysis, particularly of the respiratory center. To these effects may be attributed the extensive therapeutic employment of opium and its derivatives. The analgesic property is so decisive as to constitute its chief characteristic.

For the relief of pain, morphine has no rival, and it is this distinguishing property that makes it indispensable in the practice of medicine. The decreased perception to pain is due to the almost elective effect on the pain perception centers of the cerebrum. Apparently these centers are widely distributed, perhaps in many or all the central areas. With this decreased or sus-

*These articles are prepared under a plan of cooperation between the American Medical Association, the Committee on Drug Addiction of the Division of Medical Sciences of the National Research Council and the Division of Mental Hygiene of the United States Public Health Service. Their object is to reduce the legitimate use of addiction drugs to a minimum by replacement wherever possible with other remedies that will accomplish the desired result. The physicians of the United States are the essential group in any such attempt and it is hoped that these articles will be useful to them in their practice. The funds for this work have been donated to the National Research Council by the Bureau of Social Hygiene, Inc.

pendent function of the cerebral perception of pain, the function of the centers in the midbrain is abolished, while the reflex irritability of the cord remains practically unaffected. This analgesic effect is evident in comparatively small doses, much larger amounts being necessary to produce hypnosis.

The employment of opium for its hypnotic effect alone is open to question and is liable to severe criticism or even censure. With the almost innumerable newer hypnotics now available, there is little or no justification for the use of opium with its accompanying danger of dependence and habit formation. However, it must be said that the claims of some of the manufacturing chemists that particular preparations are proper substitutes for opium are grossly exaggerated and not justified by actual practice. This holds true particularly when relief of pain is desired, but occasionally after a faithful attempt to induce sleep with several or many of the usual hypnotics, recourse to some one of the opium derivatives becomes necessary.

With these preliminary considerations one may consider the various diseases in which the use of opium is indispensable. This is a most difficult task, as it is associated with the question of individual opinion and experience. That opium is indicated in certain diseases and is contraindicated in others, nearly all will admit, but as to its specific use there are many physicians whose opinions differ and the question remains in doubt.

It is safe to say that all will agree as to the indispensability of morphine in the hopeless cases of carcinoma, regardless of the primary site. In cases of inoperable or extensive carcinoma of the uterus, prostate, bowel, tongue, stomach or breast, with or without generalized metastasis, morphine is a gift of the gods and its judicious use in relieving pain constitutes one of the greatest services the physician can render. Not only is the patient relieved of pain but the euphoria that results is a blessing, and death, which otherwise might be almost intolerable, is made easy and comfortable.

In another group of diseases, accompanied by pain and designated by colic, morphine is the drug of choice. In this group may be included the cases with biliary, renal or lead colic. Some one of the general anesthetics, as chloroform or ether, may give the desired relief but not without the necessity of maintaining a more or less complete anesthesia to obtain muscular relaxation, with the probability of a return of the pain as soon as the drug is discontinued. Accompanying renal, hepatic, pulmonary or cardiac pathologic conditions may constitute a contraindication to the use of either of the mentioned anesthetics. Except in a few cases the use of morphine is considered only a palliative measure, as renal and biliary colic are essentially surgical, while the relief in lead colic will be required only for a comparatively short time.

The further discussion of the subject may best be accomplished by considering the various diseases according to the anatomic systems. Certain cardiovascular diseases, particularly those accompanied by pain, should be mentioned. Acute pericarditis, if the pain is severe may fail to respond to any therapeutic effort short of the administration of morphine hypodermically, to be repeated as required. Perhaps the rheumatic type, in the acute plastic stage, is the form most frequently accompanied by severe pain, although any type may belong in the group.

Difference of opinion may exist as to the necessity of employing morphine in the arteriospasmotic type of angina pectoris. While it is true that most of the cases will respond to some of the vasomotor drugs, there are instances requiring one or more doses of morphine. In the coronary occlusion type of angina, whether embolic, obliterative or thrombotic, morphine becomes imperative. In this type the anginoid attacks are prone to be severe and protracted, without much, if any, expectation of relief from the vasomotor dilators.

In the pleuropulmonary group, some of the diseases and symptoms will require consideration. Although acute plastic pleurisy, either primary or secondary to pulmonary disease, with its excruciating pain and dyspnea, responds to some extent to immobilization by adhesive straps and physical therapy, too often the desired relief is obtained only by single or repeated doses of morphine.

Acute spontaneous pneumothorax, accompanied by pain and dyspnea, requires temporary relief by morphine until other therapeutic measures can be employed.

In pulmonary diseases, certain symptoms may predominate and endanger life. Pulmonary hemorrhage from any cause, particularly the massive form accompanied by fear and anxiety, may be much relieved or benefited by a preliminary or repeated injection of morphine, this to be followed by the usual recognized therapeutic efforts, depending on the underlying pathologic condition. The dyspnea of far advanced pulmonary tuberculosis may well be classed with the hopeless cases of carcinoma, in which some relief and comfort may be had during the final days or hours. Much relief and comfort may be had in the dyspnea of primary or secondary cancer of the lung. The same is true in some cases of aneurysm compressing the trachea or a bronchus.

In the gastro-intestinal group, gastric and rectal carcinoma of the inoperable and hopeless type have already been considered. The pain in gastric and duodenal ulcers, when present, will usually respond to ulcer management and does not require special analgesics. In the event of perforation, the treatment is surgical but as a palliative measure a single or repeated hypodermic of morphine may be advantageous.

The bowel diseases, as acute enterocolitis, spastic and ulcerative colitis, diverticulitis, appendicitis and the various forms of dysentery, require their own individual form of therapy and rarely constitute a cause for special analgesics or opiates. Usually the cramps, pain and irregular bowel action in spastic colitis or a bowel management with tincture of belladonna will be relieved, but occasionally the cramps or a profuse diarrhea can be controlled only by doses of an opiate, preferably camphorated tincture of opium. If the diarrhea is the predominating complaint powdered opium may give the best results as the powder is more slowly absorbed in the intestinal tract. With the increased knowledge of the different types of dysentery there has necessarily been an improvement in the therapy. Many of the older drugs have been discarded. As in spastic colitis, when diarrhea is particularly pronounced and uncontrollable by other means powdered opium may be of service. Rectal tenesmus regardless of the cause can be best controlled or relieved by rectal suppositories containing powdered opium or morphine.

Of the remaining mentioned diseases appendicitis is surgical and often ulcerative colitis and diverticulitis also are best treated surgically. Rarely if ever, is an opiate required or justified.

Some mention should be made of typhoid and the former practice of prescribing morphine or opium in the treatment of complicating bowel hemorrhages. As the bleeding is usually due to the ulceration of the bowel, there is always the question of accompanying or developing perforation. When morphine or opium is prescribed, the symptoms and signs may be so modified as to make the differential determination more difficult or even impossible.

While the cerebrospinal group includes a considerable number of diseases only a small minority of them can justly claim the indispensable therapeutic use of opium or its derivatives. It is in the symptomatic treatment of the various psychoses, and in neuroses, psychoneuroses, hysteria and insomnia that the newer hypnotics are of such indispensable service. Even in the acute manias and in delirium tremens it is only after the bromides and chloral hydrate, paraldehyde and the newer hypnotics have failed that an opiate is permissible. It should be emphasized again that the employment of opium, or its derivatives, for their hypnotic effect alone is open to question.

As to the spinal diseases, special mention should be made of ribes dorsalis with tabetic crises and lightning pains. The use of morphine to relieve these conditions should be the last resort, as dependence and morphinism are easily produced. Epidural injections in combination with the usual syphilitic therapy have produced most gratifying results and it is only in rare instances that morphine is required.

Peripheral neuritis, local or multiple, is usually secondary to some primary pathologic condition. The neuritis may be of the alcoholic or arsenical type, perhaps due to a focal infection or a compression, as in spinal caries or a cervical rib. In each individual case the therapeutic efforts should be concentrated in an effort to relieve the primary cause.

The opium or codeine treatment of diabetes mellitus has no longer been in vogue since the advent of insulin, but, not infrequently, there is an associated diabetic neuritis. When the pains are severe and do not subside on diabetic therapy, occasional doses preferably of codeine or even of morphine may be required.

Coca leaves or the fluid extract have no justifiable therapeutic claims. The chief alkaloid, cocaine, owes its popularity to the marked local anesthetic effect produced when applied to mucous membranes or injected hypodermically. This anesthetic effect is due to the paralysis of the terminal sensory nerves or the vasomotor constriction which interferes with the nerve function.

With the advent of the newer local anesthetics, cocaine has lost much of its importance.

Formerly nausea and vomiting, with or without gastralgia, occurring in acute gastric conditions were indications for the use of cocaine, but now they are readily relieved by one of the nontoxic local anesthetics. The vomiting of pregnancy no longer is a justifiable cause for the use of cocaine, as the condition is relieved by the newer local anesthetics, dextrose intravenously or ovarian endocrines.

At one time cocaine, applied locally or by spraying, was a favorite means of giving relief in hay-fever and asthma, through its vasomotor effect on the mucous membranes. The same or better results may be had with ephedrine or epinephrine, completely displacing cocaine and the danger of habit formation.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COY FORMS TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SET ON APPLICATION.

W. A. PICKVER, Secretary

NUPERCAINE CIBA — a butyloxycinchoninic acid, γ diethylethylenediamide hydrochloride — 2 butyloxycinchoninecarboxylic acid 4 diethylethylenediamide hydrochloride. $C_{26}H_{34}N_4O_4 \cdot 4HCl$ — The hydrochloride of the base γ butyloxycinchoninic acid γ diethylethylenediamide obtained by chlorination of a chlor cinchoninic acid chloride and conversion of the latter with asymmetric diethylethylenediamine into a chlor cinchoninic acid diethylethylenediamine and subsequent heating with sodium butyrate. Nupercaine was first introduced as pericaine.

Actions and Uses—Nupercaine is a local anesthetic acting like cocaine when applied to mucous surfaces and like procaine or cocaine when injected, the action being relatively prolonged. Nupercaine is about five times as toxic as cocaine when it is injected intravenously into animals, and its anesthetic activity is correspondingly greater than that of cocaine when it is applied to a mucous surface. It is many times more active than procaine hydrochloride when it is injected subcutaneously. It is reported to have caused necrosis of tissue in one case and a condition resembling gangrene with recovery in another. Death has been reported after the subcutaneous injection of 135 cc of a solution of 1 in 1000. Weak solutions (1 in 2000) cause slight temporary vascular dilatation (avoided by the addition of epinephrine hydrochloride) followed by constriction. The usual precautions should be observed when it is injected into the spinal canal or into the urethra.

Dosage—For infiltration anesthesia solutions of from 1 in 2000 to 1 in 1000 with the addition of 0.1 cc of epinephrine hydrochloride solution to 100 cc of the solution. Not more than 100 cc of 1 in 1000 solution should be injected. For spinal anesthesia a total of from 7.5 to 10 mg ($\frac{3}{4}$ to $\frac{1}{2}$ grain) in 1 in 200 solution for sacral anesthesia, 25 to 35 cc (about 1 fluid ounce) of 1 in 1000 solution or a correspondingly smaller volume of 1 in 500 solution. The details of dosage should be learned with reference to various modifications for different applications. Aqueous solutions of nupercaine should be prepared with distilled water, as the salts present in tap water of many localities may precipitate the free base butyloxycinchoninic acid diethylethylenediamide. Alkali-free glass should be used in the preparation of its solutions.

Manufactured by the Society of Chemical Industry in Basle, Switzerland (Ciba Company, Inc., New York distributor). U. S. patent applied for. U. S. trademark 266,366.

Ampules Buffered Solution of Nupercaine Ciba 7 cc 1 200

Ampules Solution of Nupercaine Ciba 5 cc 1 1000

Solution of Nupercaine Ciba 2%

Tablets Nupercaine Ciba 50 mg

Nupercaine occurs as fine white crystalline odorless powder hygroscopic, very soluble in water, about 2 in 1, freely soluble in alcohol, soluble in acetone and chloroform, slightly soluble in benzene, ethyl acetate and toluene on warming but with difficulty in the cold. Its aqueous solution about 1 in 20 is faintly alkaline to litmus, produces a definite anesthesia on the tongue. Nupercaine melts at 90 to 94°C.

Transfer about 0.5 Gm of nupercaine to a suitable Squibb separatory funnel, add 25 cc of water, followed by the addition of 2 cc normal sodium hydroxide solution and extract with three successive portions of purified petroleum benzene using 25 cc, 20 cc and 10 cc respectively. Evaporate the combined petroleum benzene extractions to dryness, the crystals melt at not less than 64°C. Nupercaine base fluoresces with the more common oxygen containing acids. Dissolve about 0.5 Gm of nupercaine in 50 cc of water, add 0.2 Gm of potassium perchlorate previously dissolved in 25 cc of water and allow to stand several hours, the crystals of nupercaine perchlorate crystallized from water melt at 130 to 132°C. Dissolve about 0.5 Gm of nupercaine in 50 cc of water, separate portions of 10 cc each, yield a white precipitate on the addition of 1 cc of nitric acid and 2 cc of silver nitrate which after decantation of the supernatant is soluble in an excess of ammonia water, no turbidity with 1 cc of diluted hydrochloric acid and 1 cc of barium chloride solution (sulfate), no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals).

Dry about 0.5 Gm of nupercaine accurately weighed over sulphuric acid in a desiccator for forty-eight hours, the loss does not exceed 2.5 per cent. Incinerate about 0.5 Gm, accurately weighed, the residue is not more than 0.1 per cent. Transfer about 0.5 Gm of nupercaine to a 400 cc beaker, add 75 cc of water, followed by the addition of 25 cc of tenth normal silver nitrate solution and 10 cc of nitric acid, subsequently boil with continuous stirring and allow to cool in a dark place. Collect the precipitate of silver chloride on a Gooch crucible wash with nitric acid and water, followed by alcohol and ether, finally

dry to constant weight at 105 C the amount of hydrogen chloride calculated from the silver chloride found corresponds to not less than 95 per cent nor more than 97 per cent calculated to the dried substance. Transfer about 0.5 Gm of pure reagent Ciba accurately weighed to a suitable Squibb separator funnel add 50 cc of water followed by the addition of 2 cc of normal sodium hydroxide solution extract with six successive portions of chloroform using 50 cc 25 cc 20 cc 15 cc 10 cc and 10 cc respectively wash the combined chloroform solution with 15 cc of water and evaporate to a thick oil in a stream of warm air expose over sulphuric acid in a partially exhausted desiccator dissolve the oily residue in about 10 cc of previously neutralized alcohol warm slightly add 10 cc of tenth normal hydrochloric acid solution followed by the addition of an equal volume of water determine the excess of acid by titration with fiftieth normal sodium hydroxide solution using methyl red as an indicator the amount of tenth normal hydrochloric acid solution consumed corresponds to not less than 99.5 per cent nor more than 90.5 per cent butyloxycinnamic acid diethylethylene diamide calculated to the dried substance

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
W A PUCKNER Secretary

DI-CITURIN NOT ACCEPTABLE FOR N N R

Di Citurin is stated by the Chemico Biologic Laboratories to be Potassium Acetyl Citrate and in the advertising it is asserted that the product is 'a basic compound not a mixture.' In the information submitted to the Council, however, the firm states that 'the substance is acetylated Citrate of Potassium with Magnesium Salicylate present as a by-product.' Furthermore the A M A Chemical Laboratory reports that a microscopic examination of a specimen of the product revealed two distinct and separate sets of crystals one resembling potassium acetate closely, the other resembling potassium citrate. The conclusions of the Laboratory were submitted to the Chemico-Biologic Laboratories with a request for evidence that Di-Citurin is a definite substance and not a mixture. This evidence was not supplied, but the firm again emphasized the presence of relatively large amounts of magnesium salicylate as an impurity. A second specimen was submitted which apparently was quite impure and had a strong odor of acetic acid. The Laboratory concludes that the product does not have the composition claimed.

In the advertising Di-Citurin is described as 'A therapeutic agent that controls arthritis and rheumatic affections by physiologic rather than chemical action and without irritant or depressant effect.' It is stated that the pharmacological actions of Di Citurin that fulfil in a notable degree the requirements in the treatment of these affections are. An increase in the leucocytes which raises body resistance to infection. A distinctly individual action upon the filtration membranes of the kidney markedly increasing their permeability to the passage of various excretory substances of the blood, but gives no hint of the similar effects to be obtained from alkali acetates and citrates. This invites the uncritical use of the product as does also the name, which the proprietors state has been coined from 'Di' for diuretic 'cit' for citrate and 'urin' for urine.

The evidence that is presented by the firm's advertising is based on a discussion of chlorides, no account being taken of other acid base factors. Sweeping claims are made for the value of the drug in the treatment of arthritis as well as for renal elimination but no evidence is offered that the action of Di Citurin differs from that of a mixture of potassium acetate and potassium citrate or from the use of either drug alone. In the cases in which there is stated to have been a reduction of blood pressure no statement is made as to bed rest nor are simultaneous control cases given.

The advertising is largely made up of partly true but essentially misleading statements in effect it constitutes an attempt to use simple alkaline diuretics of unquestioned but extremely limited value as the basis for grotesque claims which cannot deceive any but the most ignorant. It would require many pages to discuss the advertising adequately for such a discussion must be strictly governed by the weight of available evidence, whereas the advertising is not thus limited frequently containing statements for which there is no evidence either for or against.

Di Citurin is unacceptable for New and Unofficial Remedies because its composition is not correctly declared because the therapeutic claims advanced are exaggerated and unwarranted because its therapeutically suggestive name will lead to uncritical

use and because no evidence is offered that the product possesses any advantages over a mixture of its components over a simple mixture of alkali acetate and citrate, or over alkali acetate or alkali citrate alone.

COMMITTEE ON FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COMMITTEE ON FOODS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HEFTWIG Secretary

VELVEETA

A Delicious Cheese Food Kraft Process American Cheese with added milk sugar, milk minerals and water

Manufacturer—Kraft-Phenix Cheese Corporation Chicago

Description—A cheddar cheese admixed with cream (or butter and skim milk powder), milk whey powder and salt packed in tin foil lined one half pound packages

Manufacturer—Milk from tuberculin tested cattle is pasteurized brought to a temperature of 37 C and curdled by the action of added rennet. The whey is drained from the curd. The curds are matted pressed into regular cheese molds and aged under controlled temperature and humidity conditions. The typical flavor and consistency of cheddar cheese develops during the aging process.

The drained whey is spray-dried by being forced under a pressure of 1800 pounds per square inch through small apertures into a hot air drying chamber (approximately 300 F). The dry whey falls as a powder into a hopper in the bottom of the chamber and is released into barrels.

Cheddar cheese selected as to quality consistency and flavor is finely ground and then mixed with cream (or butter and skim milk powder) whey powder and salt. The mixture is pasteurized at 145 F for thirty minutes by being forced through a specially constructed hot water jacketed pasteurizer is packed in one half pound tin-foil lined packages by automatic machinery and is immediately chilled.

About 30 per cent of the whey separated from the original milk used in making the cheddar cheese is returned to the cheddar cheese mix in the manufacture of Velveeta. Butter with skim milk (equivalent to composition of cream) is substituted for fresh cream when insufficient quantity of the latter is available.

Chemical Composition— (proximate analysis)

Moisture	44.0%
Ash	0.0
Fat (Babcock method)	2.0
Protein (N x 6.25)	15.0
Lactose (Bertrand method Mathews Physiological Chemistry page 92)	0.3
Calcium (Ca)	0.1%
Phosphorus (P)	0.1

(proximate analysis of milk whey used)

Moisture	0
Ash	0.0
Protein (N x 6.25)	1.0
Fat (ether extract)	0
Reducing sugars (calculated as lactose with water of crystallization)	7.4

Calories—

3.27 per gram
92.9 per ounce
1.486 per pound

Vitamin—Contains approximately 10 vitamin A units per gram. 75 mg of Velveeta is equivalent to 10 mg. of butter in vitamin A potency.

The vitamin content may be considered as approximately that given for cheddar cheese in U. S. Department Circular 84 (1929), Vitamins in Food Materials.

A + to -
B (all eat or not eat test data)
C (all eat or not eat test data)

Claims of Manufacturer—Velveeta a new type of cheese food richer in milk minerals and lactose than the usual cheddar cheese containing the milk whey is recommended to supplement the milk intake of growing children. It spreads well on bread and is well adapted for sandwiches and salad.

Velveeta is a good source of vitamin A.

SATURDAY MARCH 21, 1931

MENSTRUATION AND OVULATION

Most physicians are accustomed to assume that menstruation is in some way connected with ovulation in women, or, more specifically, with the fate of a liberated ovum. If the ovum is fertilized and implanted, menstrual changes are averted. Coincidentally has pointed out that the heart of the difficulty in understanding some of these fundamental features of the reproductive cycle in man obviously lies in ignorance of the time relation of ovulation and implantation with respect to menstruation. It is not known, by any direct observation, he states, when the primate ovum is discharged, the unfertilized ovum has never been observed after leaving the ovary, nor has the fertilized egg been seen early enough to give any information with regard to the earliest stages of implantation, i.e., during the first two weeks. In the lower forms the phenomenon of estrus with its sharply defined period serves as a clue to the moment of ovulation. Menstruation is by no means identical, as some have believed, with the estrus of animals. To many students it has represented "merely a violent demolition of the premenstrual uterine edifice, some days after the expected tenant fails to arrive. The only normal outcome of an ovulation is pregnancy, and the hemorrhage is viewed as a pathological result of failure in this respect."

A group of investigators² at the Johns Hopkins Medical School now venture the assertion that there is something radically wrong with the prevailing or "modern" gynecologic theory of the menstrual process, which presupposes ovulation and makes the degeneration of the corpus luteum responsible for the uterine bleeding. They have postulated that the cause of menstruation is an active one and have searched outside the ovaries for the source of the stimulus, probably hormonal in nature. Working with female monkeys they have found, as others had observed that injection of the Allen-Doisy hormone preparation causes bleed-

ing in the animals, whether normal or castrated. The effect is, however, not a direct one, for hypophysectomy abolishes the effect. But bleeding occurs in hypophysectomized as well as normal animals by injection of anterior lobe extracts or by implants of the fresh gland. This is interpreted as a direct effect. Furthermore, bleeding from the uterine mucosa is a phenomenon independent of hyperplasia, swelling, or even congestion of the tissues. The Baltimore investigators point out that it does not follow, of course, that bleeding is normally an independent phenomenon. They are fully aware of the interactions of all parts of the body, the endocrines in particular. Thus, normally in women the follicle stimulating and the luteinizing hormones come into play, ovulation occurs, the anterior lobe is stimulated, and bleeding occurs from a "prepared" or pregravid endometrium of the Hirschmann and Adler type. But, they add the stimuli coming from the ovary (or other link in the endocrine chain) may be insufficient to liberate the first two but quite adequate to liberate the hormone causing bleeding. In the absence of all these hormones—menorrhoea.

The possible absence of ovulation during long periods in which uterine bleeding may proceed seems now to be established. Hartman, Firor and Geiling allege that by their studies pointing to the action of the hypophyseal hormone a physiologic basis of uterine bleeding is for the first time demonstrated and the menstruation problem is lifted from the realm of theory and conjecture. It would seem, from the experiments on the monkey to be possible to produce bleeding in a woman much more readily than stimulating a refractory ovary, and hence a dormant uterus, into action. The gynecologist interested in promoting menorrhoea must determine what benefit the patient receives from a mere bleeding without the usual concomitant "estrous," not to mention pregravid, changes.

WORK OF THE UNITED STATES PUBLIC HEALTH SERVICE

Many factors have exerted an influence in bringing about a change in the practice of medicine. Improved modes of transportation, professional specialization, increase in hospital facilities and codification of ethical standards have contributed to this change in no small measure. However, supporting the efforts of every physician in this country, and used by him either consciously or less directly, are the vast facilities in medical research and statistical information provided by the United States Public Health Service, an institution of such manifold activities and achievements that it is difficult to evaluate its influence on present-day medicine. As is true of most government bureaus, there has been a steady expansion in its activities from a modest beginning until, at the present time, according to a recent issue of *Public Health Reports*,¹ the service

¹ Corner, G. W. Oestrus, Ovulation and Menstruation. *Physiol. Rev.* 3: 457 (Oct.) 1923.

² Hartman, C. G., Firor, W. M. and Geiling, E. M. K. The Anterior Lobe and Menstruation. *Am. J. Physiol.* 95: 662 (Dec.) 1930.

employs more than 5,000 persons with an annual budget of \$11,000,000.

In 1798 Congress established the Marine Hospital Service, the forerunner of the present Public Health Service, which name was adopted in 1912. The original purpose of the service was to provide care for sick and disabled seamen not only in seaports but wherever in the country such service was needed. In order to support this new government venture, all sailors on American vessels engaged in foreign or coastwise trade were taxed 20 cents a month. The collector of customs gathered the fees which, no doubt, accounts for the fact that the Public Health Service has always been in the Treasury Department. Gradually the activities of the Marine Hospital Service were expanded until it became a federal health service. Thus in 1878 authority was granted to the service to prevent entry of disease into the country. In 1893 a further significant step was taken when power was granted by Congress to impose quarantines in order to prevent interstate spread of all infectious and contagious diseases. Since the Public Health Service by reason of its quarantine duties was the first agency to diagnose and to become familiar with such diseases as cholera, smallpox and yellow fever, it was natural that investigations into the etiology and the disseminating agents of such diseases should become a part of the interests of the service. Congress in 1901 authorized the construction of the Hygienic Laboratory in Washington, where investigations of infectious and contagious diseases could be carried on. Further expansion included studies into the conditions that influence the spread of diseases of man, and the culmination of the work of the service along investigative lines was reached in 1930, when the name was changed to the National Institute of Health and generous appropriations were made for additional buildings and equipment. This division of research of the service likewise carries on investigations in the so-called pure sciences which promise to have a bearing on the more practical aspects of the general problem. One of the duties of this division consists of supervision and control of biologic products. Viruses, vaccines, serums, antitoxins and similar substances to the value of \$10,000,000 are supervised annually—work that requires inspections in many places in the United States and in a number of countries in Europe.

While the original purpose of the Public Health Service was to provide care for seamen, there are only twenty-five marine hospitals in this country. The policy has been to arrange for this care by contract with private hospitals. Some 300,000 persons apply annually for treatment in the marine hospitals and outpatient offices and there are from 3,000 to 4,000 sailors constantly in hospitals. More than 52,000 patients were given dental treatment during the last year. This division of the Public Health Service is charged also with the physical examination of candidates for license

as pilots and other ships' officers, lighthouse keepers, able-bodied seamen and coast guard. Marine hospitals for more than ten years have replied to radio requests for medical advice from vessels at sea. Certain of the marine hospitals have become known for their work on special diseases, notably the one at Fort Stanton, New Mexico where tuberculosis is the special interest and the National Leprosy Home at Carville, La., where the work is sociological as well as medical in character.

The maintenance of quarantine is another of the duties of the Public Health Service. The prevention of free travel of persons or animals infected with a contagious disease is one of the oldest methods whereby society protects its health. The discovery of the mode of transmission of many of these diseases has helped to facilitate the efficacy of quarantine, on the other hand increase in the extent as well as development of newer modes of travel has increased the difficulty of such control. The Division of Foreign and Insular Quarantine of the service is charged with the prevention of entrance of infectious and contagious diseases into the United States at ports of entry and also cooperates with the Immigrant Service of the Department of Labor in examining immigrants. In addition there is careful observation abroad, in conjunction with consular officers, in order that such diseases may be prevented from being transported to this country on vessels. Cholera, plague, yellow fever, smallpox and typhus fever are especially guarded against, and control measures, either applied to the person or directed against the transmitting agents, are effectively employed. The Division of Domestic Quarantine supervises the interstate quarantine, cooperates with state departments of health, controls the water supplies for drinking on interstate carriers, cooperates in maintaining efficient sanitation in national parks, and studies and suppresses epidemics arising within the country.

The accumulation, classification, interpretation and, in recent years, popularization of facts pertaining to public health is one of the functions of the Division of Sanitary Reports and Statistics. Through this work the larger aspect of national health—etiology, epidemiology and preventive medicine—are made available to the physician. The Division of Venereal Diseases has cooperated with state boards of health in preventing the spread of syphilis and gonorrhea by disseminating information through lectures and films, gathering reliable statistics on incidence and treatment, in maintaining public clinics and in determining the value of certain diagnostic measures. The Division of Mental Hygiene is interested, among other things, in the problem of drug addiction. While a small proportion of addicts are mentally normal, the larger part are abnormal in this respect and are considered by the service as problems in mental hygiene.

The present day citizen of this country accepts much as a matter of course. His very existence in great

groups in large cities is possible because of agencies which he supports, to be sure, but of the nature of which he is usually unaware. Such an agency is the Public Health Service with its long and honorable record of activity and its extraordinary awareness of the state of health of the nation. In this institution the individual physician has effective support for his labors.

PHOSPHATASE IN BLOOD AND BODY TISSUES

At present much attention is being directed to calcium in the diet. There are of course, two main reasons for this emphasis on the part of students of nutrition: first the usual American dietary has been shown to be less satisfactory in its content of this element than in most other respects while, second, there is a relatively large demand for calcium in the body, especially at certain periods in the life cycle. The normal development of bones is conventionally associated with an adequate supply of lime. However, phosphorus is likewise fundamentally involved in skeletal growth, but, since it is more plentifully supplied in the ordinary dietary, it seems to have received somewhat less attention by investigators of the biochemistry and pathology of bone development. The fact that most rations provide a sufficient supply of phosphorus indicates the variety of chemical combinations, both organic and inorganic, in which this element is presented to the body. Considerable uncertainty has existed as to the device whereby the cells in calcifying cartilage and other tissue cells remove the phosphorus from the blood, evidence has accumulated that an enzyme, phosphatase, plays an important part in this reaction.

The principal action of phosphatase consists in decomposing acid-soluble esters of phosphoric acid to inorganic phosphate. The enzyme has been shown to attack hexose phosphate, glycerophosphate, glycerophosphate and even the sodium salt of guanine nucleotide. It acts most rapidly at the unusually alkaline reaction pH 8.9. It has been found in high concentrations in growing bone, kidney and intestinal mucosa, and in less amount in the liver and the central nervous system. In a recent study, Kay¹ has shown definitely that normal blood plasma contains a phosphatase, qualitatively like the enzyme in the tissues, but present in small amount. The human kidney contains 300 times more of this factor than the same weight of plasma. The phosphatase content of the blood was examined in a variety of disease conditions. There was found little change from the normal values in diabetes, various diseases of the kidneys, arthritis or hypoparathyroid conditions and in persons with neoplasms. In some cases with thyroid involvement, and in osteomyelitis, rickets, osteitis fibrosa, osteomalacia and osteitis deformans, the phosphatase was greatly increased, being twenty times

greater than normal in some instances. Furthermore, the increase in enzyme concentration was, in general, parallel to the severity of the disease.

Taken together with certain observations on the phosphatase of normal tissues, these results with the plasma enzyme concentration in generalized bone disease indicate the possible normal behavior of these factors. It has been shown that phosphatase is not found in noncalcifying cartilage but that where calcification is taking place the enzyme is present, the more active the formation of bone, the greater the concentration of enzyme. Phosphatase occurs in embryonic bone growing in vitro. Apparently under normal conditions little of the enzyme from bones or other tissues passes out of the cells with the blood, but, when widespread breakdown of such tissues occurs, phosphatase accumulates in the blood in greater concentrations since it is only slowly excreted.

Kay has pointed out that, in contrast to the recognized changes in calcium and inorganic phosphate in the plasma in diseases of bones, far greater variations in phosphatase occur. Whether or not these newly discovered factors will facilitate diagnosis is not yet known. There is always the possibility of the practical application of enzymes to therapeutic requirements, an eventuality which in the present connection, would be particularly fortunate.

PHYLOGENETIC IMMUNOLOGIC RECAPITULATION?

Current theories of allergy and immunity are based on the assumption that normal human proteins are unchanged in specificity from the time the ovum is fertilized to its death. A different condition might have been developed if early experimenters had made the opposite assumption, a dynamic protein specificity. Mass immunizations of adults to diphtheria, scarlet fever and poliomyelitis, for example, might have been pictured as a normal primummunity, observed allergies as a result of arrested maturations, atypical differentiations or embryonic protein reversions.

Biochemical stasis is not assumed in other fields of pathology. An embryologic recapitulation of evolutionary history is postulated by many anatomists, with arrests, reversions and atypical recapitulations as the accepted explanation for numerous adult structural abnormalities. Wells and Corper² and Long³ have apparently demonstrated embryologic recapitulation in human tissue enzymes. In all adult mammals except man and the higher anthropoids there is an adenine-splitting enzyme. Fifth to sixth month human embryos contain this lower mammalian enzyme, the enzyme, however, disappearing before the ninth month of intra-uterine life, at which time the human fetus

¹ Kay, H. D. Plasma Phosphatase. *J. Biol. Chem.* **89**: 235-249 (Nov.) 1930.

³ Wells, H. G. and Corper, H. J. *J. Biol. Chem.* **6**: 469 (1909).

³ Long, A. R. *J. Biol. Chem.* **15**: 449 (1913).

apparently passes into the higher human-anthropoid type of nitrogen catabolism. A similar enzymic recapitulation is suggested by the researches of Mendel and Mitchell.⁴ They report that, in the embryonic domestic pig, nitrogen metabolism is effected without the aid of a uric acid-splitting enzyme, an intra-uterine purine metabolism somewhat resembling that of birds and reptiles. About two months after birth, uricase develops in domestic pigs, after which their purine metabolism is of the mammalian type.

The demonstration that human and animal protein specificities are not the same throughout the life of an individual is, therefore, if confirmed, one of the most significant basic contributions of the past two years. Picado⁵ reports that rabbits immunized with human serums of the 7 to 10 year age group yield antibodies quantitatively diagnostic for that age group, and that human serums of the 60-70 years age group can be similarly diagnosed. In his hands, young rabbits immunized with the blood or serum of old rabbits, give sharply defined isoprecipitins for the old-age proteins, negative reactions being obtained with youthful proteins. It is difficult to explain Picado's results without the assumption of a definite cycle of maturation of protein in each individual.

That such postulated maturations of protein possibly proceed along phylogenetic lines is suggested by recent studies of spontaneous mass immunizations. Toyoda and his co-workers⁶ report that the adult Chinese of Manchuria show but half the percentage susceptibility to Dick toxin shown by the adult Japanese, and but one forty-fifth of the Japanese percentage morbidity to scarlet fever, the two races being equally susceptible at birth. Here are two races living under practically identical conditions, subject to the same environmental antigenicities. The observed difference is easily explained on the assumption that one is here dealing with a spontaneous protein maturation and that the Chinese are hereditarily endowed with more advanced protein maturation potential than the Japanese. Thus apparently fantastic suggestion is raised to the rank of a serious immunologic theory by recent clinical studies by Friedberger and his co-workers,⁷ of the Hygienic Institute, Berlin. These investigators report the gradual appearance of apparently spontaneous maturation "antibodies" against certain noninfectious antigens in growing children, antigens, they believe, which never come in contact with human tissues. According to their interpretation, these "antibodies" are formed as a result of an hereditary general protein maturation law.

No immunologist, of course, would take the Friedberger maturation hypothesis as more than a challenge to basic research. But until the Friedberger theory is

definitely ruled out, current antiallergic therapy cannot be said to rest on a firm theoretical basis, nor can epidemiologic deductions from observed mass immunizations be assumed to be more than of tentative validity.

Current Comment

PATHOGENESIS OF OBSTRUCTIVE ATELECTASIS

The persistent study of experimental atelectasis is an indication of the importance of an understanding of the pathogenesis and mechanism of this condition to the thoracic surgeon. A situation in which the alveoli of the affected area are collapsed and contain no air is normal in the fetus, in which the aeration of the blood is effected by the maternal pulmonary apparatus, it may be brought about by compression resulting from an abnormal collection of pleural fluid, an intrathoracic tumor or massive collapse (pneumothorax), or it may result from obstruction in the bronchi. Recent studies of Corvillo and Birnbaum¹ indicate that the disappearance of the alveolar air in the atelectatic area can be accounted for by absorption into the blood. Obviously the atelectasis produced by obstruction lends itself most readily to experimental procedure. Using this device Van Allen and Lindskog² have carried out an extensive study, which has explained some controverted points and raised new questions. They observed that atelectasis did not invariably follow a mechanically successful occlusion of the air passage involved, in fact, after being convinced that the alveolar air was exhausted, they frequently observed that the lobe of the lung contained air after an interval of several hours. The authors suggest that there is free intercommunication between the structural units of the lung and that air will readily pass from one lobule to another and hence to and from an area distal to the obstruction in the bronchus, provided the blocked bronchus ventilates only a portion of the lobe of the lung. When, however, all the air passages to the lobe are obstructed, atelectasis occurs. "The development of atelectasis following bronchial obstruction must depend primarily on the rate of two processes: the loss of air and recession of air." Again, on theoretical grounds the obstruction, usually produced by chemical or bacteriologic inflammation of the bronchi, should be dislodged or moved proximally by coughing. However, at times it appears that the plug is thus actually drawn farther into the peripheral portion of the alveoli. Van Allen and Lindskog point out that only when there is a residuum of air behind the plug is coughing effective in removing it. This air passes into the alveoli either past the plug during inspiration preceding the cough or through the septums from adjacent lobules. In making suggestions for the application of the facts observed the authors advise caution lest factors in the pathogenesis of atelectasis, not yet recognized, be unwittingly promoted.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks
The American Medical Association broadcasts at 10 a. m. on Monday 10 45 on Tuesday 9 15 on Thursday and 10 30 on Saturday, over Station WBBM (770 kilocycles or 589.4 meters).

The program for the week is as follows:
March 23 Hygienic Adjustment Throughout Life
March 24 Are Modern Parents Failures?
March 26 Foothill Hero—Ten Years After
March 28 The Preschool Years

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays from 12 to 12 05 p. m., Central Standard Time.

The program for the week is as follows:
March 23 Health and Advertising
March 24 Ringworm of the Feet
March 25 Work and Health
March 26 Work and Health
March 27 Happiness and Handicaps
March 28 Happiness and Handicaps

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC.)

ARIZONA

Bills Introduced—H 203 proposes a new pharmacy practice act. Physicians apparently, are prohibited from dispensing drugs and medicines and may administer them only in emergencies. H 220 proposes to authorize the establishment of a state tuberculosis sanatorium.

Hospital News—With the completion of a laboratory, April 1, the new Sage Memorial Hospital, at Ganado in the Navajo Indian reservation, 55 miles northwest of Gallup, N. M. will be in full operation. A gift of \$50,000 from the Russell Sage Foundation supplied the funds for the new building. The hospital is conducted by the board of national missions of the Presbyterian church. The building is a two story modern structure providing for seventy-five beds. Much of the stone equipment was bought with funds given by Indians. The x-ray unit is said to be the only one in an area of nearly 50,000 square miles. The hospital maintains its own gas manufacturing plant to supply fuel gas to the diet kitchens, laboratory and sterilizing rooms.

ARKANSAS

Bill Introduced—S 220 proposes that persons who have completed the regular course of study in an accredited high school shall be eligible to enter any medical college in the state.

Society News—Drs. George E. Cannon, Hope and Arley D. Cathey, El Dorado addressed the Tri-County Medical

Society (Union, Ourachita and Columbia counties) El Dorado at the January meeting, on embolism and epidural infection of the spinal cord respectively. The Yell County Medical Society was organized January 8, Dr. Henry Lee Montgomery, Gravelly, was elected president.

Illegal Practitioner Fined—William Henry Newsom, Louann, was fined \$100 in Justice L. W. Bowers court. Cunden February 20 on a charge of practicing medicine without a license according to a report from the state medical board. Newsom claimed that he had been graduated from the St. Louis College of Physicians and Surgeons and licensed in Louisiana in 1900 and that he had been licensed in Arkansas in 1903. Newsom's attorney gave notice of an appeal to the circuit court.

CALIFORNIA

University News—The University of California Medical School will celebrate its semiannual alumni day, March 24. At the afternoon session Dr. John I. Sampson among others will speak on Therapeutic Use of Potassium in Certain Cardiac Arrhythmias. Clarence D. Jerke, Ph.D. will deliver the annual Alpha Omega Alpha Lecture on The Alchemy of Alcohol.

Probation for Narcotic Violators—At a meeting of the California Board of Medical Examiners, Los Angeles, February 25 Dr. David L. Matzke, San Francisco, was placed on probation for three years during which time he shall not apply for or have a narcotic permit or have narcotics in his possession. Dr. Walter W. Hopson, Los Angeles was placed on probation for five years. He was ordered to surrender to federal officers all narcotics in his possession.

Personal—Bennet M. Allen, Ph.D., professor of zoology, University of California, Los Angeles, has received a grant from the National Research Council to further his investigations of the glands of internal secretion. Dr. John B. deC. M. Saunders, Edinburgh has been appointed assistant professor of anatomy in the University of California Medical School. Dr. James E. Pendergrass, Clovis has been appointed health officer of Fresno County to succeed Dr. George L. Long who has held the position for several years. Dr. Harold P. Muller has been appointed city health officer of Modesto to succeed Dr. James W. Morgan. Dr. Cecil G. Newbecker has been appointed health officer of Kings County to succeed Dr. Aaron S. Torrens.

Traveling Laboratory Offered to University—The Southern Pacific Company recently offered the use of a completely equipped laboratory on wheels to the University of California Hooper Foundation for Medical Research to assist in answering emergency calls throughout the state for help in fighting epidemics. The car has been rebuilt to fill the needs of a staff of public health workers either for emergencies or for routine examinations and educational programs and is available at any time for use anywhere along the railroad lines. It has a well equipped bacteriologic and chemical laboratory, an x-ray room with facilities for developing films, a waiting room examining room quarters for two physicians and a technician, a galley and combination dining and record room and quarters for a crew of two. Karl F. Meyer, Ph.D., and Dr. Jacob C. Geiger of the foundation have already made use of the car in demonstrations before various medical associations.

COLORADO

Bills Introduced—H 129 proposes to limit the employment of drug store and pharmacy employees to an average of nine hours a day, or to not more than 108 hours in any two consecutive weeks or to not more than thirteen days in such two consecutive weeks. H 271 proposes to regulate child caring agencies and institutions.

Society News—Drs. Alfred L. Briskman, Colorado Springs, and Clarence B. Ingraham, Jr., Denver addressed the El Paso County Medical Society March 11, on 'Red Cell Sedimentation in Diagnosis and Prognosis' and 'A Consideration of Conditions of American Obstetrics, with Some Local Statistics' respectively. The Medical Society of the City and County of Denver was addressed February 17 by Dr. Alfred H. Washburn on 'Prevention of Heart Disease in Early Life'. At a meeting of the Colorado Society of Clinical Pathologists January 17 it was recommended that a prize in clinical pathology be established to be awarded annually to the student who has shown the greatest proficiency in laboratory work in clinical

pathology at the University of Colorado School of Medicine. The minimum amount of the award was set at \$25, the exact amount to be settled each year by a vote of the society. The scientific program at this meeting consisted of a symposium on undulant fever, among the speakers being Drs Philip Hillmanitz Denver, Carl W. Maynard Pueblo, Leo C. Hulsman, Colorado Springs, and Josephine N. Dunlop, Pueblo.

DELAWARE

Bills Introduced—S 163 proposes to authorize the state board of health to appoint a corps of physicians for work in connection with the public school system. Substitute for H 169 to amend the workmen's compensation act, proposes (1) to permit an injured employee to select his own physician and (2) to strike out the limit on the extent of the medical aid for which an employer is liable. S 108 to amend the medical practice act, proposes that the medical council shall consist of three separate boards of medical examiners: one board representing the Medical Society of Delaware; one representing the State Homeopathic Medical Society of Delaware; State and Peninsula; and one representing the Delaware Osteopathic Association. Osteopathic applicants are to be examined by an osteopathic board in all subjects in which medical applicants are examined, including materia medica, except that the practice of osteopathy is substituted for the practice of medicine. Apparently, all present osteopaths may receive, without examination, unlimited licenses permitting them to prescribe and administer drugs and to practice surgery.

DISTRICT OF COLUMBIA

Dr Novy Gives Kober Lecture—Dr Carrel Receives Cancer Prize—Dr Frederick George Novy, professor of bacteriology, University of Michigan Medical School, Ann Arbor, will deliver the annual Kober Lecture, March 28, at Gaston Hall, Georgetown University. Dr Novy's subject will be "Respiration of Micro Organisms." On the same evening, Dr Alexis Carrel of the Rockefeller Institute for Medical Research, New York, will receive the Dr. Sofie Nordhoff-Jung Cancer Prize of \$1,000. Baron Friedrich von Prittwitz, German ambassador to the United States, will make the presentation.

ILLINOIS

Bills Introduced—S 197 proposes to regulate the practice of massage and physiotherapy and to authorize the department of registration and education to license such practitioners to use manual, physical and mechanical measures, and all natural methods for therapeutic purposes. S 191 proposes to repeal that section of the pharmacy practice act which provides that no person may purchase, lease, acquire or establish a drug store or pharmacy except (1) a registered pharmacist, (2) a partnership, an active member of which is a registered pharmacist or (3) a corporation, each officer of which is a registered pharmacist. H 453 proposes to make it unlawful "for any person to experiment or operate in any manner whatsoever upon any living dog, for any purpose other than the healing or curing of said dog."

Society News—Drs Sandor Horwitz and William A. Hinkle were the speakers at the meeting of the Peoria City Medical Society, February 17, on "Medicine as Practiced by the Early Hebrews and Jews during the Bible and Talmudic Times" and "Anal Rectal Abscess and Fistula." Dr Noble Sprout Heaney, Chicago, spoke, March 3, on endometriosis. —Dr Nelson M. Percy, Chicago, addressed the Will-Grundy Counties Medical Society, Joliet, March 4 on gonorrhea. Dr James H. Hutton spoke, March 11, on "Endocrine Factors in and Endocrine Control of Obesity." —Drs Andrew C. Ivy and William R. Cubbins, Chicago, addressed the Sangamon County Medical Society, Springfield, March 5, on the cause of gallstones and "Fractures—Conservative and Operative Treatment." —Dr Ernest Sachs, St. Louis, addressed the Adams County Medical Society, February 9 on "Diagnosis and Present Day Treatment of Brain Tumors."

Chicago

Personal—George P. Drever, Ph.D., professor of physiology and head of the department of physiology and physiologic chemistry at the University of Illinois College of Medicine since 1900, died February 27, aged 64. Prof. Drever received his doctorate from Johns Hopkins University in 1890 and taught there for ten years. His best known research was the discovery of the secretory nerves of the suprarenal glands.

Dr Meyer to Give Hektoen Lecture—Karl F. Meyer, Ph.D., director of the George Williams Hooper Foundation for Medical Research, University of California, will deliver the seventh Ludwig Hektoen Lecture of the Billings Foundation before the Institute of Medicine of Chicago in the City Club, April 24. Dr Meyer will speak on "The Animal Kingdom—A Reservoir of Disease."

Professor Evans Will Give Bacon Lectures—Dr Herbert A. Evans of the University of California Medical School will give the annual Charles Sumner Bacon Lectures at the University of Illinois College of Medicine. The first lecture, March 31, will be given at 4 p.m. on "The Hormones of the Hypophysis" and the second, April 1, at 1 p.m., on "The Relation of the Hypophysis to the Reproductive System." These lectures will be given in the library of the college of medicine at 1817 Polk Street. The public is invited.

INDIANA

Reciprocity Rescinded—The state board of medical registration and examination has canceled its reciprocity agreement with the department of registration and education of Illinois on the ground that Illinois requires of applicants for reciprocity a clinical examination in addition to the credentials presented on application.

IOWA

Society News—Dr Louis D. McGuire, Omaha, addressed the Waterloo Medical Society, February 17, on "Sodium Amytal Compared with Other Anesthetics." —At the organization meeting of the Iowa Academy of Ophthalmology and Otolaryngology, February 12, in Des Moines, Dr Gordon F. Harlness, Davenport, was elected president, Dr Harold J. McCoy, Des Moines, vice president and Dr William F. Boiler, Iowa City, secretary. Among the speakers on the program were Drs Thaddeus A. Minassian, Des Moines; Tongue Lesion, "Differential Diagnosis Between Carcinoma and Syphilis," James A. Downing, Des Moines, "Laryngeal Diphtheria," and Cecil C. Jones, Des Moines, "Acute Suppurative Mastoiditis Bilateral with Brain Abscess."

Bill Introduced—H 398 proposes to amend that portion of the state prohibition act allowing dentists to use alcohol for the purpose of sterilization, annealing gold or other like non-beverage purposes by allowing them to use such intoxicating liquor in accordance with federal statutes or regulations or in accordance with state statutes as is necessary in their professional practice and for sterilization and laboratory purposes. H 340 proposes to amend the osteopathic practice act in several important respects. Persons treating human ailments by manipulation of the limbs, muscles, ligaments and bones in order to correct displacements and abnormalities of the body, are to be deemed to be engaged in the practice of osteopathy. Applicants for licenses to practice osteopathy and surgery in addition to showing the qualifications required for licenses to practice osteopathy alone, must (1) present satisfactory evidence that they have completed a course of study equivalent to that required for practitioners of surgery licensed under the provisions of the law relating to medicine and surgery, (2) pass the examination required of practitioners of surgery licensed under the provisions of the law relating to medicine and surgery, and (3) present satisfactory evidence that they have completed a one year's internship. Licenses to practice osteopathy are not to authorize the licentiates to give any vaccines, serum, drugs or medicines included in materia medica. Licenses to practice osteopathy and surgery, however, are to entitle the holders to prescribe and furnish such drugs as may be necessary to carry on their practice as osteopathic surgeons. Under the present law, osteopaths or osteopathic surgeons may not prescribe nor give internal curative medicines.

KANSAS

Bills Introduced—S 377 proposes that boards of education in cities of more than 120,000 may provide free medical inspection for the school children. H 636 to amend the chiropractic practice act proposes to require the annual registration of chiropractors and the payment of an annual fee of \$5.

Society News—The Wandotte County Medical Society was addressed March 3 by Drs Thomas G. Orr and Louie F. Barney on "Water and Chemical Balance in Surgery and Treatment of Acute Generalizing Peritonitis," respectively. The society was addressed March 17, by Drs Paul M. Krall on "Practical Aspect of Endocrinology," and Robert M. Isenberger, "Experimental Developments in the Pharmacology of Endocrine Gland Products."

MAINE

Bill Introduced—H 683 proposes that no person, firm, organization or corporation shall engage in the practice of any healing art without being legally licensed to do so.

MARYLAND

Personal—A sound film of Dr. John Jacob Abel of Johns Hopkins University School of Medicine, Baltimore, lecturing on the relation of pharmacology to chemistry is being made under the auspices of the Chemical Foundation of New York and Johns Hopkins University.—Dr. Maurice C. Pincoffs was recently elected president of the Mental Hygiene Society of Maryland.—Dr. James MacFadden Dick, chief of staff of the Peninsula General Hospital, Salisbury, was presented with the 1930 Salisbury Award, which is a gold medal given annually to the citizen who is considered the greatest benefactor to the community.

Bills Introduced—H 232 proposes that when the immediate removal of the body of a deceased person who has died from natural causes is necessary, removal from the place of death may be authorized by the registrar of vital statistics or his deputy without a certificate of death from the attending physician if that physician is not available. H 261 proposes a new osteopathic practice act. It defines osteopathy as that system of the healing art which places the chief emphasis on the structural integrity of the body mechanism as being the most important single factor to maintain the well-being of the organism in health and disease. Two types of licenses are proposed: (1) a license to practice as an osteopathic physician and (2) a license to practice as an osteopathic physician and surgeon. Applicants for licenses to practice surgery are to be examined in surgery by the osteopathic board. Osteopathic physicians are to observe and be subject to all state and municipal regulations relative to reporting births and deaths and all matters pertaining to the public health with equal rights and obligations as physicians of other schools of medicine, and such reports must be accepted by the officers of the department to which such reports are made. Osteopathic physicians or osteopathic physicians and surgeons are furthermore, under this bill, to have the same rights as physicians and surgeons of other schools with respect to the treatment of cases or the holding of offices in public institutions.

MASSACHUSETTS

Bill Introduced—H 1175 to amend the workmen's compensation act, proposes to define incapacity as such incapacity for work as results from a physical injury arising out of and in the course of the employment of the employee but not including the results of a preexisting disease.

License Restored—The board of registration in medicine reports that the license of Dr. Robert E. Conlin, Somerville, to practice medicine in Massachusetts was restored, Dec. 11, 1930. The license was revoked Feb. 3, 1927, on account of the performance of an abortion (THE JOURNAL, April 23, 1927, p. 1328).

Society News—Dr. Charles G. Mixer, Boston, addressed the Greater Boston Medical Society, February 3 on 'Role of Obstructive Lesions in the Urinary Infections of Childhood'.—Dr. Frank H. Washburn Holden, delivered the George Washington Gay lecture at Tufts Medical School, Boston, March 4, on 'Role of Ethical Conduct in the Successful Medical Career'.—Dr. Samuel R. Meaker addressed the William Harvey Society, Boston, March 13 on 'Social Aspect of Gynecology'. Drs. Herbert S. Hutchinson, Milford N. H., and Henry A. Christian will address the society, April 10 on 'The Old and New in General Practice'.—Dr. Edward M. Hodgkins, Boston, addressed the Watertown Medical Club, March 2 on 'Changing Conception in the Operative Treatment of Inguinal Hernia'.

MICHIGAN

Bill Introduced—S 74 proposes to regulate the practice of cosmetology and to permit practitioners among other things to remove superfluous hair from the upper part of the body by the use of electrolysis, depilatories, waxes or tweezers.

Prizes for Essays on Industrial Medicine—The board of directors of the Michigan Association of Industrial Physicians and Surgeons has announced a competition for essays on subjects bearing on industrial medicine or surgery. The honorarium offered for the first prize essay will be \$50, and for the

second best \$25. The essays must contain a minimum of 1,000 words and a maximum of 3,000. The object of this competition is to encourage interns to emphasize reparative surgery while serving under the direct or competent surgeons. All interns and resident house officers in Michigan hospitals are eligible. Essays must be sent to the secretary of the Michigan Association of Industrial Physicians and Surgeons, Dr. Frank A. Poole, 620 State Office Building, Lansing, by April 1.

MINNESOTA

Society News—Dr. Chas. Roy Murray, New York, addressed the Hennepin County Medical Society, February 4 on 'General Treatment of Fractures'.—The Ramsey County Medical Society formally opened its new quarters and library rooms, February 27. Dr. Oscar W. Holcomb, president of the society, made the opening address. Drs. John M. Armstrong, Henry Longstreet Taylor, St. Paul, and Alfred J. Brown, Omaha, also spoke.—Dr. Frank I. Burch, St. Paul, gave an illustrated address on strabismus before the Washington County Medical Society, February 10.—Drs. Walter E. Camp, Minneapolis, and Elmer M. Jones, St. Paul, addressed the Minnesota Academy of Medicine, Minneapolis, March 11, on 'Pathology and Pathogenesis of Ocular Melanomata' and 'Pulmonary Enteritis' respectively.

Bills Introduced—S 355 if enacted would apparently repeal the provision of the pharmacy act that allows any general dealer whose shop is more than two miles from a drug store to sell any commonly used medicines or poisons that have been put up by a registered pharmacist for that purpose. S 621 to amend the chiropractic practice act proposes: (1) to allow the board of chiropractic examiners and the Minnesota American Chiropractic Association to determine the annual license fee to be paid by chiropractors; (2) to record chiropractors all the rights and privileges of other physicians in all matters pertaining to the public health, "including methods of natural healing or physical therapy except prescribing internal drug"; and (3) to add to the present causes for the revocation of licenses the claiming of superiority over any other chiropractor and failure to designate to the public by using terms or letters Doctor of Chiropractic or D.C., that the chiropractor is practicing under a chiropractic license. H 499 proposes to authorize critics of the fourth class to establish and maintain city hospitals. H 890 to amend the optometry practice act proposes to eliminate from the act the statement of certain practices now designated as unlawful such as itinerant vending of spectacles and the sale of eyeglasses in an established place of business, not under the supervision of a duly licensed optometrist or physician.

MISSISSIPPI

Society News—Drs. Francis M. Smith and Leon S. Tippecott, Vicksburg, addressed the Issaquena-Sharkey-Warren Counties Medical Society, February 10, on 'The Carrier and Contact Problem' and 'Why Examine the Urine?' respectively.

Counties Named for Health Units—The establishment of full time health units in Lauderdale and Pike counties has been assured, it is reported, as a part of the public health program of the Commonwealth Fund. To supplement the fund's appropriation of \$22,500, Pike County gave \$5,000, the town of McComb, \$2,900, and the towns of Magnolia, Summit and Osyka, each \$200. Figures were not mentioned for the Lauderdale unit. It is also planned to provide a central field unit for rural health work with headquarters in Jackson. This work will be done by the fund in cooperation with the state board of health. Mississippi is the third state to be selected by the Commonwealth Fund for cooperative health work, similar projects having already been started in Tennessee and Massachusetts.

Provisional Approval of Medical School—Early in July, 1930, reports were received indicating that sweeping changes had been made, probably through political maneuvering in the faculty of the University of Mississippi School of Medicine. The Council on Medical Education and Hospitals of the American Medical Association called the attention of the governor of Mississippi to the fact that the institution recognized by the Council no longer existed in fact and that before a new institution could be recognized it would need to be thoroughly inspected. This was followed however by the prompt restoration of most of the original personnel to their positions on the medical faculty. At its business meeting, Oct. 15, 1930, therefore, the Council voted that the approval of this medical school be held in abeyance until the effect of the recent changes could

be determined. Since that time the Council has received considerable correspondence from prominent physicians and others in Mississippi requesting the Council to hold the approval of this school in abeyance until the next governor and legislature of Mississippi are elected which will be in January, 1932, after which it is expected that favorable developments will occur. After due consideration the Council, at its meeting February 15, voted that the approval of the school be continued provisionally pending further developments.

MISSOURI

Society News—Dr Virgil F. Simpson, Louisville, Ky., addressed the Jackson County Medical Society, March 10, Kansas City on "Mendelian Law in Medicine."—Among others, Dr Kerwin W. Kimball gave an illustrated address on 'Newer Conception of the Function of the Thyroid' before the Kansas City Southwest Clinical Society, March 10 and Dr Edwin H. Schorer spoke on Diagnosis and Management of Pneumonia in Children."

Bills Introduced—S 345 proposes to repeal the workmen's compensation act. S 377 proposes to authorize the establishment of a hospital for convicts suffering from tuberculosis and other lingering diseases. S 378 proposes to create a division of mental diseases in the state board of health. H 483 proposes to abolish the licensing of assistant pharmacists and to provide that persons now licensed as assistant pharmacists may make application to the board of pharmacy prior to Dec. 31, 1931, and be licensed as registered pharmacists without examination. S 222, to amend the workmen's compensation act proposes that the employer shall be liable for such medical aid as shall be reasonably required to be rendered the injured employee for the first ninety days after the injury in a sum not exceeding \$750 and thereafter such additional medical aid as the compensation commission may determine to be necessary. S 419 proposes to require that all drugs of coal tar origin, intended for either internal or external human use be plainly labeled with the true English name and to show that they are of coal tar origin and with a statement of the dangerous effects of their use and the names of at least two active antidotes. The provisions of the bill, however, are not to apply when such drugs are prescribed by a licensed physician. H 594 proposes to provide for the sexual sterilization of certain inmates of state institutions.

NEVADA

Society News—Dr Joseph Marion Weldon, Mobile, Ala., addressed the Washoe County Medical Society, Reno recently on toxemias of pregnancy. At the same meeting Dr George R. Smith read a paper prepared by Dr Philip F. Schneider, Evanston, Ill., on the hormone test for early pregnancy.

Bills Introduced—S 77 proposes to regulate the practice of barbering and would if enacted, permit such practitioners to remove superfluous hair by the use of electrolysis, depilatories or tweezers. A 101 proposes to include marihuana among the substances classed as narcotics within the meaning of the narcotic act. A 161 proposes to repeal the law authorizing counties to establish and maintain public hospitals.

NEW JERSEY

Society News—Dr Felix Baum, Newark, addressed the William Pierson Medical Society, Orange February 20 on "Modern Tuberculosis Problems with Special Reference to Treatment."—Dr Aaron S. Price, New York, addressed the Summit County Medical Society, January 27, on "The Clinical Interpretation of Differential Blood Count."—Dr Ernst P. Boas, New York, addressed the Atlantic County Medical Society, March 13, at Atlantic City on "Rheumatic Fever."

Health at Trenton—Telegraphic reports to the U. S. Department of Commerce from eighty-one cities with a total population of 36 million for the week ended March 7, indicate that the highest mortality rate (257) appears for Trenton and the rate for the group of cities as a whole, 138. The mortality rate for Trenton for the corresponding period in 1930 was 165 and for the group of cities 138. The annual rate for the eighty-one cities for the ten weeks of 1931 was 142 as against a rate of 134 for the corresponding weeks of 1930. Caution is necessary in the interpretation of these figures, as weekly figures fluctuate widely. The fact that some cities are hospital centers for large areas outside the cities or that they have large Negro populations may tend to increase the death rate.

NEW MEXICO

Bills Introduced—S 117 proposes to regulate the practice of chiropody defined as the local, medical, mechanical, or surgical treatment of ailments of the human foot, except through the use of the knife (such as amputation of the foot or toes) the use of anesthetics other than local, and the use of drugs or medicines other than local antiseptics. It proposes to create for this purpose a board of masseur chiropody, to consist of one chiropodist and two medical practitioners. S 94 proposes a new state narcotic control act.

NEW YORK

Bills Introduced—S 993 and A 1362 propose to create in the state department of health a division of orthopedics and a division of cancer control. S 1047 proposes that each local registrar of vital statistics shall be paid 50 cents, and each physician and midwife 25 cents, for each birth certificate registered and 25 cents for each death certificate. S 1069 proposes to regulate the practice of barbering. A 1421 proposes to provide that each certificate of birth shall contain a photograph of the finger prints of the mother and the foot prints of the child. The impression is to be taken as soon after the birth as is practicable. A 1500 proposes to authorize the licensing of nurses registries in New York City by the mayor. A 1571 proposes to make it unlawful for any person in any way to distribute bichloride of mercury, mercuric chloride or corrosive sublimate, except on the written prescription of a licensed physician.

Report on Effects of Noise in Industry—Results of a study to determine the effects of noise on the hearing of industrial workers have been published recently by the Bureau of Women in Industry of the New York state department of labor. Tests were made with an audiometer on 1040 workers in seven factories and in two groups of clerical workers. Deafness was found in 246 or 23.7 per cent. Of this number 91 had some history of ear trouble that might have caused the deafness. Only 155 remained therefore in whom the condition might be related to their work. The greatest number of deafened persons were found in the group of workers subjected to the greatest amount of noise. Most of these, 66 out of 96 worked in a factory making tin cans in a room dominated by the noise of a stamping machine. In the 155 cases of deafening without any history to account for it 69 occurred in persons between 21 and 30 years. Of workers employed less than one year, 6 per cent were deafened without a history of disease to account for it. Among those employed between one and five years the percentage was 16.1 but in the next group those exposed for between five and ten years it was 12.8. Thereafter the percentage increased up to 26.9 per cent for those exposed for more than twenty-five years. The investigators pointed out however, that advancing age was probably a factor in this increase. At the conclusion of the study the investigators recommended (1) that tests of hearing be made on all new employees, (2) that periodic examinations be made where there is an undue amount of noise, (3) that certain types of machines be isolated and (4) that adequate ventilation be provided to remove vapors which were found to have an effect on the hardening of cerumen in the ears of workers.

New York City

Society News—Dr Joseph Colt Bloodgood, Baltimore will address the Medical Society of the County of Queens, March 24, instead of March 6, as noted in THE JOURNAL, March 14.

Resolution Opposing Coffey-Humber Cancer Institute—A resolution adopted in January by the New York Academy of Medicine, deprecating a proposal by the Better Health Foundation to establish a laboratory at Huntington, L. I., for research on the Coffey-Humber treatment of cancer with extract of suprarenal cortex was made public at a hearing, March 10, before a special committee of the state board of social welfare. The academy believed the establishment of such an institute to be an unwise move. Citing the experience that followed the announcement of this treatment in California, when many hopelessly ill persons abandoned treatments known to be beneficial and made great sacrifices to get to the Coffey-Humber clinic yet were not much benefited the academy recommended that these physicians follow the plan used by Banting and Best in establishing the value of insulin. This would place the Coffey-Humber extract in the hands of competent scientists and physicians who would, under the best

facilities, conduct scientific studies of the effects both clinically and experimentally. The resolution concludes:

A few patients carefully observed with detailed study of all reactions will yield far more valuable results than a less controlled use of the remedy on a number of patients too large for such a study. For these reasons the New York Academy of Medicine further believes that there is no need for the creation of a new experimental and clinical institute for this study, since ample facilities are already available in established cancer institutes and hospitals.

Hospital News—A compressed-air lock for the treatment of compressed air disease will be added to the equipment of Metropolitan Hospital on Welfare Island, having been provided for with a \$15,000 appropriation by the board of estimate, March 6. It will be used also for the study of the effect of compressed air on the human system, and will be operated under the direction of Dr. Thomas McG. Lowry.—The \$2,000,000 ten-story Columbus Hospital was officially opened, February 11. It has been under construction for two years and has a capacity of 250 beds. It was opened for patients March 1.—The department of urology of the New York Hospital recently received \$197,081.80 by the will of the late Gustavus L. Lawrence. Proceeds from this sum will be applied to the needs of the department and will be kept in a separate fund to be known as the Gustavus L. Lawrence Fund.—The Jacob Fuhs Auditorium in the pathologic institute of the United Israel Zion Hospital, Brooklyn, was formally dedicated March 1 with an address by Dr. Frank D. Jennings, representing the Medical Society of the County of Kings. Dr. Fuhs, who died in 1927, was for many years on the staff of the hospital.—A new laboratory building for clinical diagnosis and research in pathology, bacteriology, pharmacology and physiology was dedicated, March 5, at the Long Island College Hospital, Brooklyn. The building constructed at a cost of \$125,000, is the gift of Dr. John Osborn Polak, professor of obstetrics and gynecology in the medical college. Dr. Willard C. Ripple, dean of the Columbia University College of Physicians and Surgeons, made the dedicatory address.

NORTH CAROLINA

Society News—A Radiological Society of North Carolina was recently organized at Durham with Drs. John K. Pepper, Winston-Salem, as president; William T. Raney, Jr., Fayetteville, vice president; and Major I. Fleming, Rocky Mount, secretary. The next meeting will be held during the annual session of the Medical Society of the State of North Carolina at Durham, April 21. It is intended that two scientific meetings will be held each year and an annual business meeting during the session of the state medical society.

Bills Introduced—S. 280 proposes to amend the law requiring male applicants for marriage licenses to present certificates from physicians certifying the absence of venereal disease, of tuberculosis in infectious stages and of epilepsy by requiring such a certificate from both male and female applicants. S. 333 proposes to permit any two or more counties to establish a district hospital home for the aged and infirm in lieu of separate county homes. H. 716 proposes to allow physicians to prescribe medicinal liquor under the same general restrictions as appear in the Volstead Act. H. 692 proposes to prohibit the distribution of hypnotic drugs except on written prescriptions of licensed physicians. Hypnotic drugs are defined to include "sulphonmethane, sulphonethylmethane, diethyl sulphonedrethylmethane, diethyl barbituric acid (barbital), and chloral hydrate or any solution thereof containing 20 grains or more to the fluidounce."

OHIO

Dr. Reid to Succeed Dr. Heuer at Cincinnati—Dr. Mont R. Reid, associate professor of surgery in the University of Cincinnati College of Medicine, was appointed head of the department of surgery by the trustees of the university, March 3. He will succeed Dr. George J. Heuer, who will go to New York at the end of the present academic year to become surgeon-in-chief of the New York Hospital and professor of surgery in Cornell University. Dr. Reid graduated from the Johns Hopkins University School of Medicine in 1912.

Bills Introduced—S. 263 proposes to provide medical and surgical treatment and hospital care for indigent persons in university hospitals and to utilize such hospitals in the care and treatment of wards of the state. S. 263 to amend the workmen's compensation act proposes to define injury to include any injury received in the course of employment or any disability caused by illness or disease which arises out of or is the result of such employment. H. 585 proposes to create a board

of chiropractic examiners and to regulate the practice of chiropractic, defined as the science of diagnosing, locating and correcting interference with nerve transmission and physiological response without the use of drugs or major surgery."

Society News—Dr. Louis J. Karnosh, Cleveland, addressed the Toledo Academy of Medicine, February 6, on 'The Neurology of Emotions'.—Dr. Joseph A. Capps, Chicago, addressed the Cleveland Academy of Medicine, February 20, on 'Plural Pericardial and Peritoneal Pain'.—Dr. William H. Weir, 'Technic of Hysterectomy'.—Dr. Edwin von Graff, professor of obstetrics and gynecology at the faculty of medicine, University of Vienna, Austria, conducted clinics at the meeting of the Eighth District Medical Society, Zanesville, February 19.—Dr. Leonard A. Strick spoke on spinal anesthesia before the Lorain County Medical Society, February 10. Dr. Gerald S. Shibles, Cleveland, among others, addressed the society, January 13, on etiology of the common cold.—Dr. Louis N. Katz, Chicago, addressed the Hancock County Medical Society, Findlay, February 4, on the use of the electrocardiogram in clinical medicine.—Dr. Frank Semsheimer, Cincinnati, spoke on prevention and early diagnosis of contagious diseases in children before the Clark County Medical Society, Sidney, February 11.—Dr. Roy W. Scott, Cleveland, presented an address before the Summit County Medical Society, Akron, March 5, on 'Heart Disease: Chief Barrier to Longevity'.—Dr. George M. Curtis, Chicago, addressed the Academy of Medicine of Cincinnati, January 19, on 'Chloride Metabolism in Relation to Surgery'.—Dr. Harry E. LeFever, Columbus, addressed the Fayette County Medical Society, Washington Court House, January 8, on diagnosis and treatment of head injuries.—Drs. Percy S. Pelouze, Philadelphia, and Harold N. Cole, addressed the Academy of Medicine of Cleveland, March 20, on 'Gonorrhea and Its Treatment' and 'Bismuth Salts in the Treatment of Syphilis,' respectively.

PENNSYLVANIA

Bill Introduced—S. 324 proposes to regulate the practice of chiropody and create a board of chiropody examiners. The practice of chiropody or podiatry is defined as the diagnosing of all ailments of the human foot, and the medical, surgical and mechanical treatment of such ailments except the correction of deformities requiring the use of the knife, amputation of the foot or toes or the use of any anesthetic other than local.

Society News—Dr. Morris A. Slocum, Pittsburgh, among others, spoke on 'Cultivation and Sterilization of Fly Larvae and Their Use in the Treatment of Chronic Osteomyelitis' before the Allegheny County Medical Society, March 17.—Dr. Thomas B. Holloway, Philadelphia, delivered the Stewart Memorial Lecture, March 10, before the Pittsburgh Academy of Medicine on 'Certain Pathological Conditions About the Chiasm with Special Reference to Pituitary Adenoma'.

Philadelphia

Society News—Dr. Alfred F. Hess, New York, gave the Frederick A. Packard Memorial Lecture before the Philadelphia Pediatric Society, March 10, on 'Ultraviolet Irradiation Irradiated Ergosterol and Irradiated Foods'.—Dr. Collier F. Martin delivered the weekly seminar lecture under the auspices of the Philadelphia County Medical Society, March 13, on 'Diagnostic Symptoms in Anorectal Disease'.—Dr. Warren H. Lewis, Baltimore, presented a motion picture of tissue cultures of human and mammalian tumor cells before the Pathological Society of Philadelphia, March 12.—The Philadelphia Psychiatric Society devoted its meeting, March 13, to a discussion of schizophrenia; speakers included Drs. James Hendrie Lloyd, Joseph C. Yaskin, Bernard J. Alpers, Edward A. Stricker and Carl D. Bond.

SOUTH CAROLINA

Bills Introduced—H. 375 proposes to provide dental clinics for the public schools of the state and to authorize the employment of school dentists. H. 554 proposes to discontinue the school of pharmacy at the University of South Carolina after the scholastic year 1930-1931. H. 573 proposes to allow physicians to prescribe intoxicating liquors under the same general restrictions as appear in the Volstead Act.

Society News—Dr. Horton R. Casparis, Nashville, Tenn., addressed the South Carolina Pediatric Society at Columbia, January 14, on 'Recent Advances in the Treatment of Infectious Diseases'. Other speakers included Drs. Thomas D. Dott, Jr., Columbia, on 'Intra-cranial Injuries of the New-

Born" and Richard M. Pollitzer, Greenville. "Acute Lymphatic Leukemia." Dr. Edward W. Barron, Columbia, was elected president of the society.

SOUTH DAKOTA

Bill Introduced—H 323 proposes to levy annual occupational taxes of from \$10 to \$50 on licensed and practicing physicians and surgeons.

Hospital News—St. Mary's Hospital, Pierre, which was recently dedicated has a capacity of 100 beds, and was built at a cost of more than \$200,000.

TEXAS

Bills Introduced—S 421 proposes to authorize the establishment of a tuberculosis sanatorium for Negroes in a location to be selected by the board of control. S 483 proposes to create a commission to inquire into and report on the number, distribution and condition of crippled children and physically disabled adults in the state. S 488 proposes to record liens to hospitals and physicians on any insurance benefit due persons treated by physicians or hospitals. H 202 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic. H 295 to amend the law requiring the licensing of maternity hospitals and homes, proposes to make it a misdemeanor (1) to operate such an institution without a license from the state board of health, (2) to sell or traffic in babies, and (3) to maintain in said institutions tuberculous or mentally unbalanced persons, or persons suffering from infectious or contagious diseases. H 407 proposes to create the Dallas State Hospital, to be composed of the Dallas Psychopathic Hospital and the State Cancer and Pellagra Hospital.

UTAH

Society News—Dr. William L. Bender, San Francisco addressed the Box Elder County Medical Society, Brigham recently, in a joint meeting with the Cache Valley and Weber County Medical societies on "Anterior Poliomyelitis and Encephalitis."—Dr. Charles C. Johnson, Salt Lake City, presented a paper on "Pharmacologic and Toxic Effects of Sodium Nitroprusside" before the Utah County Medical Society, Provo recently.

Bills Introduced—S 43 to amend the workmen's compensation act, proposes to authorize employers to enter into agreements respecting hospital benefits and accommodations and medical and surgical services nursing and medicines, and services to be furnished of licensed practitioners not using drugs or medicines." H 151, to amend the narcotic act, proposes to make it unlawful for any person to unlawfully procure or make, execute, sign, or to advise, assist, or aid in the false or fraudulent execution of any order or prescription, or to forge the name of any duly licensed physician, dentist, veterinarian or other duly authorized person to any order or prescription for any of the narcotics or drugs enumerated in the act.

VIRGINIA

University News—The Stuart McGuire Lecture for 1931 will be given, March 25, at the Medical College of Virginia, Richmond by Samuel Alfred Mitchell, Ph.D., professor of astronomy and director of the Leander McCormick Observatory at the University of Virginia on "Eclipse Hunting in the South Seas." This lectureship was established in 1930 in recognition of the services to the college, to medical education and to surgery of Dr. McGuire, who is emeritus professor of surgery.

WASHINGTON

Illegal Practitioner Fined—C. Irving Grieger was arrested in Chubbuck, February 17, charged with practicing medicine without a license. He was fined \$25 and costs. Grieger who also posed as a chiropractor, has appealed, it is reported.

New Hospital Bans Drugless Healers—The drugless healers of Seattle and King County were informally notified February 26 it is reported that they had lost their right to be permitted to practice in the new \$2,500,000 Harborview Hospital, which was dedicated on the same date. The new city and county institution has a 450 bed capacity.

Bills Introduced—S 184 proposes to authorize counties or counties and cities to operate hospitals jointly. S 204 to amend the chiroprody practice act, proposes that a person fitting recommending or selling corrective shoes arch supports or similar mechanical appliances shall not be deemed to be

engaged in the practice of chiropody. S 228 proposes to make it unlawful to deliver to the same person in any twenty-four hour period more than 4 ounces of sweet spirit of niter.

WEST VIRGINIA

Personal—Dr. Andre Crotti, Columbus, Ohio, delivered the first annual memorial lecture of the Medical Review Society, Huntington January 29, given in honor of the late Dr. Claude Aubrey Latham on goiter. The Medical Review Society is described as a local organization founded ten years ago by local members of the Cabell Medical Society, the membership being restricted to twenty and by invitation. Dr. Latham's death was the first in the organization and a series of public lectures was instituted as a memorial.

Bills Introduced—H 377 proposes to require male applicants for marriage licenses to file an affidavit that they are free from contagious venereal diseases and that they believe their proposed mates to be likewise free. In the event that the marriage license clerk is not satisfied as to the matters alleged in said affidavits he may require certificates from duly licensed physicians. H 51 proposes to create a board of barber examiners and to regulate the practice of barbering. S 146, to amend the chiropody practice act, proposes to define chiropody as the medical, mechanical and surgical treatment of the ailments of the human hand or foot (except the amputation of the foot hand toes or fingers) without the use of anesthetics other than local. It is to include also the fitting or recommending of appliances, devices or shoes for the correction or relief of minor foot ailments provided, that the act shall not be deemed to prohibit the sale of foot appliances and remedies by retail dealers. H 359 proposes to require all hospitals, under certain circumstances, to treat the indigent sick and to allow any hospital rendering such service to set off the charge against taxes due on real estate or personal property.

WYOMING

Society News—Dr. John R. Nilsson, Omaha, addressed the Sweetwater County Medical Society recently on fractures. He also showed a motion picture on "Bloodless Cesarean Section." Dr. Russell H. Kanable, Basin, recently addressed the society on "Diagnosis and Treatment of Incipient Tuberculosis."

GENERAL

Society News—At the annual meeting of the Pacific Coast Surgical Association at Victoria, B. C., February 27-28, Dr. Rex E. Smith, Los Angeles, was elected president. Drs. Charles M. Fox, San Diego, Calif. and Raymond E. Watkins, Portland, Ore., vice presidents and Dr. Edgar L. Gilcrease, San Francisco, secretary reelected. The seventh annual meeting of the association will be held, Feb. 26-27, 1932, at Coronado, Calif. There will be two days of clinics in Los Angeles preceding this meeting. Dr. James Tate Mason, Seattle, gave an illustrated address at the annual association dinner on "Seattle's First Physician."

Diplomas Lost—Two graduates of the University of Tennessee College of Medicine, Drs. Charles D. Brunt, New Castle, Pa., and Bedford F. Floyd, Jr., Kilgore, Texas, have recently reported the loss of their diplomas. Dr. Brunt reported that his diploma, issued June 10, 1929, disappeared from his room in a hospital after he had placed it under some magazines to flatten out a wrinkled corner. Dr. Floyd stated that his diploma, issued June 16, 1927, was left at the home of his mother in Senatobia, Miss., in June, 1928, and when he looked for it in December, 1930, he was unable to find it. Dr. Floyd's Tennessee license to practice medicine was lost at the same time.

Itinerary to Philadelphia Meeting of Otolaryngologists—The American Board of Otolaryngology is sponsoring a special itinerary beginning with its examination in Los Angeles, May 27, and concluding with the meeting of the American Otolaryngological Association in Briarcliff, N. Y., June 17-19. The itinerary, via the Union Pacific System and Wabash and Pennsylvania railroads includes the meetings of the Pacific Coast Society in Los Angeles, May 28-30; the American Laryngological Rhinological Otolaryngological Society, St. Louis, June 3-5; American Bronchoscopic Society, St. Louis, June 6; American Medical Association, June 5-12 in Philadelphia; American Laryngological Association, Atlantic City, June 15-17; and the American Otolaryngological Association in Briarcliff, N. Y., June 17-19. Further information may be obtained from Dr. William P. Wherry, secretary, American Board of Otolaryngology, 1500 Medical Arts Building, Omaha, Neb.

Recrudescence of Cerebrospinal Fever

Cerebrospinal fever, which has recently been reported in various parts of the world, has now been observed in England. Periodic increases in the incidence of this relatively rare disease are not unusual. The total notified cases in England and Wales in 1929 was 650, which is above the average, and in 1930, 660. In the present year 230 cases have already been reported among civilians. They have shown a scattered distribution over thirty-six counties, but there has been some concentration in the West Riding of Yorkshire, where seventy-nine cases have occurred. In the army a local prevalence of influenza has been associated with a number of cases of cerebrospinal meningitis. Thus since January 31, thirteen cases have been notified in the Aldershot Command and six among the Air Force at Uxbridge. At Aldershot, with the exception of a fatal case in a nurse in attendance on patients suffering from the disease all the cases occurred in men who had had influenza. They belonged to various units and did not come from any one regiment or building. Eight of the Aldershot cases have been fatal. In a London barracks a guardsman has died from the disease. The frequent association of the disease with military establishments is a curious phenomenon for which no explanation is forthcoming since the hygiene of the buildings and the good health and physique of their occupants are undeniable. However, during the war years it was found that when more room was given the men to live and sleep in the incidence of the disease fell.

The Rule Not to Move a Patient Before Giving First Aid

A schoolmistress recently was run down by a motorcycle in London and, while lying on the ground and being attended, she was run into by an automobile. She appeared to be suffering from concussion and had scalp and face wounds. While the attendant was bandaging the wounds as she lay on the roadway an automobile was driven through the onlookers, crushed the patient, and carried her several yards. She died two hours after admission to a hospital. The driver, a captain of artillery, was arrested for being drunk while in charge of an automobile and was tried for manslaughter but was acquitted. The jury said that there was negligence on the part of the ambulance men, while the judge added that it was wrong practice to bandage people in the middle of the road. Sir William Willcox, the toxicologist, who was called on behalf of the defendant, gave a similar opinion. The Central Public Health Committee of the London County Council, which controls the ambulance service, has made a reply stating that this opinion is not supported by medical teaching or by those who have experience of ambulance work. It maintains that a principle of first aid is that the person seriously injured should be allowed to remain in the place where he has fallen until examined by a physician or a person skilled in first aid. It is held to be dangerous to move a patient who has sustained severe head or spinal injuries before first aid has been given, and in this case a local physician who saw the patient after the first accident was of the opinion that she should not be moved. Representatives of the two ambulance organizations—the Order of St. John and the British Red Cross Society—expressed to the committee the same opinion which is laid down in their textbooks. It is added that the number of street accidents dealt with by the council's ambulance service in 1930 was 34,529 that this method had been employed ever since the ambulance service was started and that the present case was the first in which a second accident occurred while the

patient was being treated. Therefore notwithstanding the opinions expressed at the trial, the council will keep to the established practice, which is in accord with current medical opinion and the advice of the council's own medical officers. They consider that it would be highly dangerous to issue an instruction to the ambulance staff that the injured should not be treated where they fall.

Another Attempt of Osteopaths to Obtain Recognition

In the house of commons a labor member has introduced a bill to regulate the practice of osteopathy and to prescribe the qualifications of osteopaths. He said that recognition had already been granted in forty-seven of the states of the United States. The bill was opposed by another labor member, a physician, who argued that the proposed standard was not sufficient to guarantee the public against serious mistakes. However, the bill was read a first time. A few years ago a similar attempt was made but the bill was defeated by a considerable majority. However, the fact was revealed that the osteopaths had a large number of supporters in the house. There is toleration in this country unlike the continent for all sorts of irregular practitioners but it does not seem likely that two orders of practitioners for the treatment of all maladies will be recognized.

The London Clinic and Nursing Home

Probably no city in the world presents such a contrast in the provision for illness as London. On the one hand there are the voluntary hospitals where the poor have at their disposal every resource of modern medicine and surgery and the services of the best specialists of the day. Nothing comparable can be obtained outside the hospitals except by the rich. There remains the great middle class whose circumstances or whose pride remove them from the hospital class who have to put up with makeshift accommodation and are excluded from all the advantages of equipment and coordination found in the hospitals. The advance of medical science has meant more and more elaborate equipment and greater and greater need for coordination of services and therefore has aggravated the evil. Modern specialist treatment requires a building specially adapted for the investigation and treatment of disease, organized on modern lines and provided with laboratories and x-ray equipment. After much effort, extending over twelve years such a building containing rooms to suit all classes of paying patients is now nearing completion. The great difficulty was that there is a strong feeling against the financing of nursing homes by physicians, while no financial group was prepared to undertake a risk in which physicians refused to share. A solution agreeable to both parties was reached. A company was formed to erect a building consisting of a nursing home, for the financing of which the company would be responsible and a number of consulting rooms, the lease of which the physicians might purchase without breach of medical ethics. This assured the company of satisfactory medical support without involving the physicians in financial responsibility for their affairs. The building is in the neighborhood of Harley Street the consulting center of London. Special care has been taken to protect the patients against noise and vibration. The steel uprights that support the building are embedded in a system of padding which insures complete absence of vibration. The building has been designed with great care and according to the best expert views. To obtain the latest information on modern equipment and organization a committee visited the most modern hospitals of Europe and America and it is claimed that the clinic will be an advance on anything in existence. A wide range of accommodation between small single rooms and private suites will meet the varying requirements of patients. A special feature is provision for maternity cases and for children. For

the former a special floor has been specially equipped with arrangements to insure absolute quiet and privacy. The children will be accommodated in a special wing, so arranged that each child can, if necessary, be accompanied by its own family nurse, while a solarium opening directly on the south side of this wing will give every opportunity for fresh air and sunshine. The nursing staff will be so large that special nurses can be supplied at a low charge. There will be two resident medical officers. But it is part of the design that every patient can remain in touch with his own physician. In connection with the group of physicians, who occupy the consulting rooms, there is a plan of combined work, so that patients of moderate means may be saved multiple consultations, which involve so much expenditure of time and money.

Research on Prevention of Infantile Paralysis

Dr E. Weston Hurst, of the Lister Institute of Preventive Medicine, has injected the virus of acute poliomyelitis into the horse and found that the immune bodies produced in its blood will protect monkeys inoculated with the disease. As monkeys are much more susceptible to the disease than man it is concluded that a means of preventing the rendering of the latter immune has been discovered. Dr James Collier, a neurologist, announced at a meeting held at St. George's Hospital that this was an epoch-making discovery.

PARIS

Experiments with Bacteria on Bullets

For a long time, it was thought that bullets from a revolver and, especially, projectiles from an army rifle, could not transport infectious germs because the projectile was sterilized by the high temperature to which it was raised by the friction of the air during its transit. Infections found in wounds caused by projectiles were attributed to bits of clothing carried along by the projectile or to germs present on the skin. Dr. Piedelievre, agrégé professor of legal medicine at the Faculté de Paris, with the collaboration of Dr. Guy, performed a series of experiments, which he reported recently before the Société de médecine légale. They used the bullets of three different types of army rifles and a Browning revolver of heavy caliber. The bullets were sterilized in a flame and then covered with a coating of cultures of *Bacillus prodigiosus*. The barrel of the weapon was sterilized by first firing off a blank cartridge. The targets were packages of carded cotton wrapped in three thicknesses of paper and then sterilized in the autoclave. Before the shooting, the outside wrapping was slit open on three sides and folded back like a shutter, and then folded down again after the shooting, before the package was transported to the laboratory. The fibers of cotton along the path of the bullet furnished regularly positive cultures after implantation in liquid or solid culture mediums. *Bacillus prodigiosus* was chosen by reason of its being innocuous. But Dr. Piedelievre, who is planning to perform these experiments with other microbes, is convinced that proof has been furnished that projectiles may be infectious, irrespective of the length of the trajectory and their degree of heat in transit. Back of the packages of cotton were placed steel plates against which the bullets struck, and it is well known that, by the impact heat is produced, so that the temperature reaches several hundred degrees; nevertheless the cotton adjacent to the impact was infected. Doven pointed out twenty years ago that when a person fires a bullet into his head that reaches the brain the prognosis is not especially unfavorable if the revolver and the bullet are new. The wounds are always fatal if the person with suicidal intent used a revolver that had been lying in a drawer for a long time, where the bullets had become charged with dust.

Difficulties in the Removal of Tattoo Marks

When the recent war opened, tattooing had not been practiced, for a century, except among troops stationed in Africa, who acquired the habit from the Arabians. As these troops have been composed of men compelled, as a disciplinary measure, to perform military service outside of France, and since, after completing their period of army service, many of them continued their bad practices, tattooing became a stigma of evildoers. At the same time it furnished the police a means of identifying criminals. During the war, however, many soldiers amused themselves by getting tattooed. Most of these men, after the war, sought some means by which the tattoo marks could be removed as they were rather ashamed when they went to the public baths or the seaside bathing beaches. Likewise, many evildoers had the same desire, in order that the means of identifying them might be removed. It is extremely difficult to remove tattoo marks. All the minute particles of lampblack introduced with the India ink with which the needle of the tattooer is charged have to be removed from the skin, one by one. When undertaken by skillful dermatologists—even though they may have made a specialty of such removals—it is a long and delicate process, and the final result is usually that white cicatricial spots have replaced the bluish spots of the tattooing. The best procedure is perhaps that introduced by Dr. Variot, which consists in applying a vesicatory, removing the epidermal membrane from the formed blister and rubbing the denuded skin vigorously with a strong solution of silver nitrate. One region after another is taken up; if the tattooed area is large for the inflammatory reaction produced is considerable. The number of persons desiring to have tattoo marks removed has given rise to a type of charlatanism. Dr. Locard, director of the police technical laboratory in Lyons, has published the results of an inquiry into the fraudulent practice by which charlatans take advantage of their clientele. One charlatan created an organization with representatives in all parts of France. He employed a lotion of secret composition in which Dr. Locard recognized the presence of phenol. The results were lamentable, but the victims, for fear of ridicule, did not complain. One, however, who had been burned, with resultant large sloughs leaving scars, brought suit. The police discovered at the office of the healer a supply of nitric acid. As a result of his inquiry, Dr. Locard demands that operations for the removal of tattoo marks be left entirely to physicians and that such operations performed by a person who is not a graduate physician be considered by the courts as illegal practice of medicine.

Opening of a Museum by Public Welfare Department of Paris

Dr. Mourier, director of the Assistance publique of Paris, has announced to the municipal council the opening of a museum in which will be exhibited many interesting things belonging to the archives of the department, some are several centuries old. The department has inherited equipment from all the ancient hospitals of the capital. Many persons formerly bequeathed their possessions, including their homes and all that they contained, to the poor—that is to say, to the hospitals and to the Assistance publique. Naturally only articles that had some documentary, artistic or historical interest have been preserved. One will find in the museum rare pieces of furniture, paintings by old masters, religious books with costly colored prints derived from the chapels of hospitals, and from the pharmacies a collection of pottery of all epochs which, from point of variety and richness, has no counterpart elsewhere. There is also a whole library of documents, acts, and the like which were formerly piled up in storerooms but which now are available to the public for inspection and study. A fire in 1871 during the Paris insurrection destroyed a part of this material but what has been preserved has inestimable value. The museum will be installed in the buildings of the Pharmacie centrale des

hospitals, which is the former Hotel des Miramiones, being located on the Quai de Gesvres, on the bank of the Seme, directly opposite the Notre Dame cathedral

The Pasteur Institute of Algeria

The Pasteur Institute of Algeria, which was created in 1910 published recently a report on its activities. During 1929, 126 missions of a scientific or technical nature were carried out, by the personnel of the institute, in the Sahara region, France, Italy and the three departments of Algeria. The institute performed nearly 10,000 medical, veterinary or agricultural analyses, the rabies service treated 2,229 patients, 523 of whom belonged to the department of Algiers, 696 to the department of Constantine and 992 to the department of Oran, including 18 from Morocco. Besides the antirabic vaccine supplied to patients, the institute delivered 3,148,131 doses of vaccine, serums, ferments and various microbic products, 1,417,611 for medical use, 1,551,561 for veterinary use and 178,859 for agricultural use. About 22,000 persons, mostly children, have been given quinine treatment. During the campaign of 1929, 126 inquiries or journeys were made, 24 lectures were delivered, and nearly 1,000 chemical analyses were performed.

BERLIN

(From Our Regular Correspondent)

Feb. 9, 1931

Increase in Diphtheria in Europe

Professor Burgers, director of the hygienic institute in Königsberg, reports in the *Deutsche medizinische Wochenschrift* that since the low ebb of diphtheria in Germany in 1923 (19,599 cases) the curve has risen to 38,604 for 1930 up to October 25. There may be said to be an epidemic incidence of diphtheria, especially as there must be a large number of unannounced cases, as against the reduced number of susceptible children compared with the prewar period. The question arises as to whether this is a transient increase or the rising tide of a large wave. As to the causes of this manifestation, the range of diphtheria morbidity in other countries deserves attention. A survey reveals that, in Germany and in most other countries, the low ebb of diphtheria was recorded in 1923. From then on there has been a distinct upward trend of the figures. In Holland, however, the figures have fluctuated, in Japan there was a distinct upswing in 1929, and in New York State the curve is downward until 1926, though 1927 shows a distinct increase.

As an important combative measure against the spread of diphtheria, Burgers urges parents to note the first signs of throat disorder, if any children are suspected, to keep them away from other children and to summon a physician. It is equally important that the physician should make a diagnosis on the basis of the clinical observations and not wait for the results of the bacteriologic diagnosis, especially in cases in which early injection of serum is necessary. The question is to the value of prophylactic inoculation, in addition to antitoxin, and the method of immunization by inoculating with the Lowenstein ointment or with other preparations, merits closer attention. As such a method is likely to become more popular with the public and is less expensive than other methods, it would likely be easier to carry out, from a practical point of view. But one must never allow the idea to gain ground that any known immunization method will afford absolute protection. Only the aggregate of all combative measures will help to reduce the number of victims which is still much too high.

Infantile Paralysis in Baden

The outbreak of infantile paralysis that occurred in Alsace in late summer 1930 extended in some instances to the neighboring regions across the Rhine, although the morbidity was not as great as in Alsace. The most important observations in this field were made by Professor Moro, the director of the Heidelberger Universitäts Kinderklinik. In Baden 180 cases were notified

and it is estimated that, if the unrecognized and the abortive cases are included, the total morbidity would be three times as great. Forty-seven cases were admitted to the clinics, there was only one death. Bananas play no part in the transmission of the disease, nor in cattle, feathered animals or flies be justly incriminated (note the severe epidemic in winter in Sweden). The causative agent is probably invisible and it is resistant to cold. Cultures kept for six years under refrigeration were still virulent. The incubation period in monkeys is from seven to ten days. The disease occurs chiefly in early childhood, 70 per cent of the cases were in children from 6 months to 5 years old. The rural population is more susceptible. Regions that are visited by an epidemic are spared the next time. After contact with the virus, immunity may be acquired by unrecognized infection. Only rarely does a patient infect a brother or a sister, in a series of seventy-one cases there was not a single instance of such infection among siblings. In outbreaks in buildings or in families, the several cases develop simultaneously, it is not a question of contagion through contact. The patient himself plays a subordinate part in the transmission. The disease appears to spread chiefly through healthy or mildly ill intermediate agents. The status lymphaticus constitutes a predisposition to the disease. Disinfection of excreta is necessary because of the theory that the disease may be spread through the drinking water, and also on account of the observation that the infection sometimes follows the river courses. The virus is present equally often in the intestine and in the nasopharynx. Ingestion infection has not to be sure, been demonstrated. In threatened regions, intramuscular injection of adult's blood or serum, for example, 20 cc. of fresh blood from either parent or of mixed blood from the two parents is recommended as a simple, harmless and effective form of prophylaxis. Protection for a period of about four weeks may be expected.

Study Tour to East Africa

Prof. F. K. Kleme of the Robert Koch Institute for Infectious Diseases in Berlin received an invitation from the missions of the white fathers in former German East Africa to undertake a two-year study tour of that region. The invitation with the aid of the *Notgemeinschaft der deutschen Wissenschaft* and the *Zentralkomitee zur Bekämpfung der Tuberkulose*, was accepted. The purpose of the tour was to extend and to supplement former observations on trypanosomiasis and to solve certain questions of theoretical importance. As Kleme reports, the present mandatory government combats the disease chiefly by removing the natives from infested regions and settling them in healthy localities. The disease is thus kept under control and a sudden increase is scarcely to be feared. Since the discovery of Bayer 205, Kleme considers that no further progress in the treatment of trypanosomiasis has been made. Veterinary medicine, however, has attained further progress in the treatment of cattle that have become infected since Hans Schmidt succeeded in preparing a nonirritable form of antimony and potassium tartrate.

Two Thirds of Population Beneficiaries of Health Insurance

The number of persons who were holders of health insurance during the year 1929 rose to nearly 23,000,000. To this number must be added the members of families who are insured through the head of the family, which makes about as many more, thus today about 46,000,000 persons, or more than two thirds of the population of Germany, are the beneficiaries of health insurance. According to the records, the number of sick benefit associations has decreased still further. There were only 7,362 as compared with 7,426 the previous year. On the other hand, the number of members was increased by about 300,000. This denoted a slowing up in the increase of insured persons, the chief reason for which lies doubtless in the increased number of persons out of work. But the total receipts of the sick benefit

associations have increased more rapidly than the membership, owing to wage increases and higher monthly dues. The average annual dues were 98.23 marks (\$23) per member, or 61 per cent more than the previous year. The total contributions exceeded the sum of 2,000,000,000 marks (about \$500,000,000). The expenditures increased in the same proportion as the receipts, and also exceeded \$500,000,000. The principal item of expense was the cost of sick benefits, which amounted to 1,740,000,000 marks (\$435,000,000), or 86.5 per cent of the total expenditures 78 per cent more than in 1928. Also the administrative costs have risen of late years, though the percentage for 1929 was about the same as in 1928. The excess of receipts over expenditures for 1929 was about 800,000,000 marks (\$200,000,000). The reserve funds have been increased, during the past three years, by about 1,500,000,000 marks (\$375,000,000). It is apparent, therefore, that social health insurance in Germany is a financially sound undertaking.

Death of Professor Trendelenburg

The death of Paul Trendelenburg, professor of pharmacology and director of the Berlin Pharmacologic Institute, after a protracted illness, at the age of 46, is announced. After studying under W. Straub, he became, through the reputation of his publications, *ordinarius* at an early age, at first in Rostock and later in Freiburg, where he succeeded Straub when the latter accepted a call to the University of Munich. In 1927, he removed to Berlin as the successor of Heffter. His work on the prescribing of medicines passed through several editions in a short time. But, more particularly, the first volume of his work on the hormones has met with wide approval from scientists. In nobility of character he excelled as he did in the quality of his scientific contributions. He was always ready to serve when called on in the interest of science and the practice of medicine, and he always welcomed to his institute students from foreign countries. Germany and science have lost in him a notable investigator and teacher.

Jan 15, 1931

Annual Meeting of Orthopedic Society

At the twenty first annual session of the Società italiana di ortopedia in Rome under the chairmanship of Prof. Dall' Vedova the first official paper, "The Surgical Treatment of Tuberculosis of the Knee," was presented by Drs. Mezzani and Fusari of Trieste. The speakers brought out that although the surgical method has been condemned and the conservative method adopted by the majority of surgeons, in osteo articular localizations of tuberculosis, cases of surgical intervention have not been lacking. The chief objection to the conservative methods is that they require a long time. The speakers reviewed various methods, old and new, used in the treatment of tuberculosis of the knee. Synovectomy, if performed as the sole intervention in arthritis, is an insufficient operation which experience has long since condemned. In synovitis it has always given worse results than are secured by heliotherapy. In gonitis tuberculosa in young men arthrectomy with arthrodesis has been recommended by Hibbs and Sever. This was formerly advised by Codivilla and confirmed by proofs of recoveries presented by Giuliani at the Congress of Surgery in 1927. This resection was said to be economical and takes account of the special conditions of the skeleton in evolution on that account they prefer usually the typical resection. In osteoarthritis of the adult, one must place confidence in resection. The speakers prefer to intervene at once instead of trying first a conservative treatment. For amputation a limited field is reserved today. Amputation should be resorted to (1) to get rid of a focus of infection in a patient in advanced tuberculous toxemia (2) to control a grave suppurating mixed infection and (3) when resection has failed. They explained the modern methods

of conservative surgery, among others, that of Menciére, the subcutaneous evacuation of Vignard, the Robertson-Lavalle operation, the lateral splints of Dupuy De Frenelle. The common characteristic of all these types of intervention is the use of the bone graft. The speakers tried periarterial sympathectomy in five cases with unsatisfactory results. They consider that this method is not effective in osteo articular tuberculosis. In closing Drs. Mezzani and Fusari said that in synovitis the treatment should remain conservative, in pure osteitis, exercise may arrest the disease and prevent an articular invasion, in osteoarthritis the therapeutic program will depend on the age of the patient. In children the treatment will be conservative, in adolescents should be applied, in selective cases the new conservative methods. In adults, surgical treatment should at present be regarded as the rule, the operation of choice being resection. In advanced age amputation is the only course left.

Several further communications were presented. Delitalà of Venice reviewed his experience in forty six cases of tuberculosis of the knee. In forty-two cases he practiced resection and the patients recovered with ankylosis, in four cases, amputation was necessary.

Marghiano of Genoa reported good remote results (observed after fifteen years) secured with an autoplasmic bone graft in a case of gonitis. Pasquali of Bologna recited the results obtained at the Istituto ortopedico Rizzoli in the period 1899-1930, during which 156 resections were performed in 383 cases of tuberculosis of the knee. The statistics show that in tuberculosis of the knee resection is the preferred treatment in adults, whereas it is contraindicated in the child. The posture of the resected knee that presents the most advantages functionally and esthetically is that in slight flexion (about 5 degrees).

During the general discussion that followed, Calandra of Palermo spoke on sympathectomy in the treatment of tuberculosis of the knee which is widely employed in his institute. He contended that when careful judgment is used in the selection of cases sympathectomy combined with other modes of treatment will accelerate recovery. He thus treated favorably thirty cases out of thirty-two.

Prosthetic Apparatus and Orthopedic Appliances

The official paper on the second topic Recent Progress in Prosthetic Apparatus and Orthopedic Appliances was presented by Prof. M. Camurati of Bologna. For prosthetic apparatus of the lower limbs the so-called European idea (the use of leather) has been abandoned since 1915 in favor of the American plan (the use of wood). The wooden limbs are durable, are easy to apply, and render excellent service. In the final prosthetic apparatus the weight bearing foot must be proximate to the median plane of the body and the superposition of the articular axes of the lower limb must be such as to assure the greatest stability to the wearer. In wooden prosthetic apparatus there are the temporary type and the permanent or esthetic type. There are many kinds of prostheses that have great value for example the hospital prosthesis in the manufacture of which little wood is used but chiefly fascii of plaster. The value of a prosthetic apparatus depends on its functional capacity which is determined not only by its intrinsic qualities but also by the character of the patient more especially his mental state and the nature of the stump. The speaker described certain types of prostheses of the inferior limb used at the Istituto Rizzoli in Bologna 13,277 specimens of which were supplied during a period of thirteen years. As prosthesis of the upper limb, the speaker prefers from the standpoint of practical utility, the more simple apparatus in which one finds also the best adhesion of the appliance to the stump.

Galcazzi of Milan asked the opinion of the official speaker on hard aluminum which has come into vogue in Germany and France. Camurati on the basis of experience in the laboratories of the Istituto Rizzoli with other appliances made of

aluminum and hard aluminum, expressed the view that these materials do not have sufficient resistance. Galeazzi demonstrated his mechanical apparatus for the treatment of torticollis and cervical scoliosis. Formi of Bologna reported on massive autoplasmic treatment in the management of pathologic fractures resulting from bone cysts. Tancredi of Rome demonstrated his personal contribution to the study of the physiopathology of the respiratory mechanics in scoliosis.

After numerous other communications, the convention adjourned, having chosen Milan as the next meeting place. Professor Galeazzi was elected president. The topics on the program will be (1) The Present Indications for Orthopedic Treatment in the Sequels of Infantile Paralysis, and (2) Bone Cysts.

The Death of Professor Cattaneo

Prof. Cesare Cattaneo, director of the Clinica pediatrica of the University of Milan and of the Children's Hospital, died suddenly. He was president of the Società italiana di pediatria and one of the chief supporters of the idea of considering nripiologia as a distinct specialty.

International Congress of Urban Hygiene

The second Congresso internazionale di tecnica sanitaria e igiene urbanistica will be held at Milan April 20-26, 1931, under the chairmanship of Prof. G. Lenno, senator. The program will be divided into the following sections: (1) physiology, human pathology and microbiology in their relations to sanitary engineering; infections in the city and in the country; disinfections; (2) urban sanitary technique: hygiene of the street and of transportation facilities; protection against the noise of the street and the vibrations of houses and of industrial establishments; (3) sanitary technique of construction work, hospitals and sanatoriums, apartment houses; (4) sanitary technique and hygiene in the rural districts and in the colonies; (5) sanitary technique in the shops and laboratories; elimination of industrial refuse; and (6) sanitary legislation, creation and functioning of municipal officials in charge of the hygiene of homes and public buildings in the large cities; social provisions. An exhibit of equipment will be organized in connection with the congress.

The Red Cross During the Past Two Years

Senator Filippo Cremonesi, president of the Italian Red Cross, has published an account of the activities of that body during the years 1928 and 1929. In connection with the crusade against tuberculosis four sanatoriums were enlarged and reorganized, and 1,889 patients were admitted in 1928 and 2,084 in 1929. Aid was given to tuberculous persons of Italian origin residing in foreign countries. In child welfare, in addition to having increased the work of numerous preventoriums, summer colonies and ambulatoriums for children, the administration of the Sanatorio di Ariocia was assumed. Likewise, the sanitary service in the rural schools of central and southern Italy was organized. During 1929, 1,837 children in the antitrichinosis dispensaries were given assistance. The crusade against malaria was intensified, partly as a result of agreements reached with the general management of the public health service and with the Opera nazionale dei combattenti. By government order all the first-aid services connected with other similar associations were absorbed by the Red Cross. The government has entrusted to the Red Cross the sanitary defense of the civil population against asphyxiating gases. The problem of the transportation of the sick and wounded was studied and solved by the adoption of a new type of auto ambulance. The preparation and work of voluntary nurses have been improved. The number of schools for them has been increased to sixty-three. All the nurses, voluntary and professional, have been brought into one organization called 'l'Amghia delle infermiere' for the purpose of completing their training.

TURKEY

(From Our Regular Correspondent)

Ankara, Feb. 1, 1931

The Certification of Specialists

In the last twenty years the faculty at Haydar Pasha and the Gulhane Hospital, which is a teaching hospital, has produced a number of specialists who have supplemented their studies by graduate work at European institutions, where they have received special certificates. While most specialists have devoted years of study to their special line, there are others who have worked at it for only a short time. The latter have increased in number, and in order to provide the public with efficient service the council of state drafted regulations, which have been adopted by the government.

Specialist certificates having been issued by institutions approved by the Turkish medical school or by the ministry of health and social assistance, or those issued by a hospital or laboratory of a foreign country, recognized by the Turkish medical faculty, are divided into three main groups, clinical, laboratory or hygiene specialist certificates. There are nine clinical specialties: internal medicine, surgery, mental and nervous diseases, diseases of the eye, nose, ear and throat, venereal and skin diseases, pediatrics, obstetrics and gynecology, and urology. There are six laboratory specialties: bacteriology, pathologic anatomy, medical chemistry, legal medicine, radiology and physical therapy. To procure a specialist certificate in one of these groups at least three years, of laboratory specialists at least two years, and of hygiene specialists a total of four years of special study are required. The four years of the hygiene specialists are spent in the study of bacteriology, parasitology and infectious disease, and in hygiene laboratories. Those occupied with bacteriology and parasitology spend three years. Time spent in study previous to the publication of this regulation is recognized. Physicians who have been permanent assistants in a hospital or laboratory, and those who before receiving their diploma have held internships at the Turkish medical faculty, may take the examination for the hygiene specialist certificate after three years, for the medical and surgical specialist certificate after two years and for laboratory and other specialist certificates after one and a half years.

Candidates are examined at the medical school in the presence of the professors under whom they have studied and a jury of two other professors elected by a committee of the medical faculty. Examinations at other institutions approved by the ministry of health and social assistance are held by a jury to be elected from among the clinical or laboratory heads of those institutions; this jury is subject to the approval of the ministry of health. The examinations are to be theoretical and practical, the former in writing. Candidates who have procured specialist certificates in foreign countries must present themselves for examination before a jury of two professors to be elected by the faculty committee. Physicians holding a specialist certificate that has been procured in Turkey and who at the same time hold one that has been procured in a foreign country are to have the latter recognized without another examination. Specialist certificates of candidates who have spent the required time in special study at clinics or laboratories of institutions other than indicated by the medical faculty or the ministry of health are not valid unless recognized by an institution indicated by the medical faculty or the ministry of health. Candidates with certificates not recognized must spend three months in a clinic or laboratory indicated by the medical faculty or the ministry of health and then be examined before a special jury. Physicians who before the publication of these regulations have, without interruption, done specialist work at an institution and who do not possess a specialist certificate and who within one year from the publication of these regulations present themselves before a board of examiners with their certificates and diplomas are to receive the specialist certificate without having to go in.

for another examination if their knowledge and skill have been investigated and not found wanting.

Certificates are made out either to candidates skilled in one of the medical branches and capable of directing a clinic or laboratory of that branch, or to specialists who engage in private practice. Only these two kinds of specialist certificates are made out. Physicians who do not possess the first mentioned certificate are not permitted to conduct the clinic or laboratory of a government, municipal or private institution. The ministry of health may issue to physicians whose certificates permit of private practice only (if those physicians have spent three years of uninterrupted study in their special branch) a license that will permit them to perform the specialist duties of their own clinic or laboratory. Certificates that have been issued before the date of publication of these regulations, by the medical faculty or by the clinics of the Gulhane Hospital, the graduate school for army physicians, or from recognized foreign institutions and which have been in accordance with these regulations, are valid.

Hospitals Supplied with Radium

The year that has passed has seen little change in the medical profession in the Union of South Africa. The acquisition of adequate supplies of radium by the three provinces of the union Transvaal, Natal and the Cape has been made possible by public subscription, initiated, thanks to the support given by the lay press by individual physicians. The department of public health declared that radium was a matter falling exclusively within the province of the hospitals with which public health as a department, has nothing to do. Local funds were established with the object of purchasing small quantities of the element, it being supposed, by the public, the government and the profession alike, that radium could be handled and cancer patients treated with radium by any general practitioner. Those who knew something about the matter vigorously protested against this interpretation of the situation and urged that the Australian example should be followed and that the government should purchase and control the radium. The minister of public health, Dr Malan, who although a doctor of theology and not of medicine is sympathetic toward the profession and has on many occasions followed the hints given him in health matters, found himself unable to fall in with this suggestion and the government has not contributed a penny toward the radium funds. These have been raised by the public, at the urge of medical men. Indeed, the publicity given to the radium campaign has shocked some of the older colleagues, who still imagine that a medical man must not give his opinion on anything appertaining to medicine, and especially to treatment, outside the privacy of the sick room or the consulting room. A prominent colleague, who quite rightly, had on returning from Europe given an interview to the lay press in which he had frankly detailed what was being done overseas in radium therapy, was indicted before our medical council on a charge of advertising. Fortunately the council saw no evidence of advertising in what it deemed to be a matter of public duty and said so quite cheerfully. Medical men here are not yet educated to realizing that the public demands knowledge of certain facts and that it is as futile for the doctor to refuse to give these facts as it would be for the ignorant lay journalist to supply them second hand. All reputable daily papers in the union now have friendly medical men who advise them on medical matters and this policy of asking the profession to give its views on matters affecting both it and the public can be heartily commended. The result of the publicity given by individual physicians to radium therapy has been that our main hospitals are now well supplied with radium and that the public has been roused to a sense of its responsibilities.

On the other hand there has been a falling off in the interest displayed by the profession in what may be called medical politics. This is perhaps due to the fact that there is at present no urgent matter on which the profession is likely to be consulted. Old age and invalidity pensions are not on the legislative program, and the vigorous campaign planned to deal with them has been abandoned. From the published reports of the meetings of the federal council which may be looked on as the mouthpiece of the profession one gets the impression that nothing of really serious import has been dealt with during the year. The council established a committee on general practice which might have been of considerable value but the committee appears to have done nothing during the year, and to the lay public the federal council is practically unknown. The medical council on the other hand, which is a statutory body containing several lay members is well known and has lately published its regulations framed under the medical dental and pharmacy act. These regulations deal with the registration of medical men and students.

Poverty and Disease

The past year has been the driest and most trying year that the union has experienced since 1910. The rainfall has been phenomenally low and many farmers have been unable to raise anything. The general depression has affected all sections of the community but in the drought stricken areas the medical practitioners are especially affected as they are more often called on to attend patients sickness having increased, while their fees are never paid. In one district a physician has received no payment on account from private patients for many months. All he has had to exist on is the monthly check from the government his honorarium as district surgeon. The ensuing poverty has reacted on the health of the people, particularly in country areas and in the poorer urban quarters which are being thronged by vagrants emigrating from the country. Malnutrition caused by bad foodstuffs and insufficient vitamin content of the food is common. Pellagra is on the increase. Xerophthalmia, formerly rarely seen, is now common enough. Acrodynia is not uncommon, and where it occurs its prognosis here is apparently much less favorable than elsewhere. The juvenile population in the poverty stricken districts subsist on maize meal and sweet potatoes. They suffer extensively from carbohydrate overfeeding. The native population, which lives almost exclusively on mealies and has given up largely, its nutritious millet meal is badly off. The death rates among children appears to be slightly on the increase but that, in the circumstances is less to be regretted than is the general lowering of the standard of vital resistance, which is almost everywhere apparent. It has been repeatedly urged that the government should devote special attention to a study of the factors that militate against the health of the European and native child, but so far there does not seem to be any co-ordination of child welfare effort. Much energy and money are being wasted in dealing with this matter on haphazard lines.

The Law and the Quacks

The medical dental and pharmacy act forbids any one who is not registered as a practitioner to do anything, 'special appertaining' to the practice of medicine. Heretofore it has been almost impossible to prosecute a quack of whom there are many for South Africa is probably a *dominion paradise* for the faith healer the Christian scientist and the 'patent medicine' vender, and supports its own brand of the genus in the shape of the Kaffir witch doctor. Lately the supreme court at Pretoria has allowed the appeal of a quack from a magistrate's court decision. The judge declared that where the quack did something for the purpose of humoring his victims in order to induce them to accept treatment the price for which would vary according to the affluence of those undergoing it it could not be said that he was doing something appertaining to the practice of medicine. This particular quack gave his victim a

confection of dates and senna, but the judge held that that was not necessarily "medicine." He told another victim that his eyes were poisoned 'by injections for malaria' and charged 10 guineas for restoring his sight. The judge did not think that the sight testing was "appertaining to the practice of medicine" and said so. The judgment has given rise to some discussion and it is felt that a test case would be desirable. At present the uncertainty as to what the words of the act really mean allows the quack practically a free hand.

UKRAINE

(From Our Regular Correspondent)

Odessa, Jan 16, 1931

Popularizing Cremation in Ukraine

The first crematory was opened in Moscow in 1920. It was impossible to open a crematory before the revolution, as the holy synod—the supreme ecclesiastical authority in the Russia of the czars—was opposed to it because of religious considerations. The Moscow crematory did not begin functioning until some years after it was officially opened. About 1930 the idea of building crematories in the Ukraine arose. The government has already given its sanction to the projects of crematories in Charkoff and Odessa and in Charkoff a crematory is already being built. The price of a cremation will be about one rouble (50 cents), which includes the cost of a wooden coffin, special clothing and boots. Before the cremation takes place the relatives may perform all the religious rites they wish. Afterward the ashes are placed in a special urn, which the relatives of the deceased may take away with them or leave at the crematory in a columbarium. The experience of the Moscow crematory shows that usually cremation is not accompanied by any religious rites, the most popular funerals are the so called civil funerals, in which the clergy does not take any part.

The Antireligious League has organized this year a circulating exhibit with the aim of popularizing in the Ukraine the idea of cremation. This exhibit displays much interesting material and is accompanied by special lecturers, who speak on cremation. It has visited Odessa and will visit all the Ukrainian centers. A large number of persons have attended the exhibit.

The Health Resorts of Odessa

Odessa, and particularly its mud health resorts, the Koujalmik and Hadjibei 'limans,' occupy a prominent place among the health resorts of the Ukraine. They are situated on the shores of firths—arms of the sea separated from it by a flat elevation of the ground. As a result of evaporation due to the constant influence of the air and the sun, the water in these firths—the "rapa"—is saturated with a concentrated solution of salts, having from 45 to 27 Baume degrees, and contains about 765 Gm of salt in 1 liter of water.

The bottom of the firth is covered with a thick layer of mud or slime, formed as a result of the dying out of the Black Sea's ancient fauna, as well as of the rising of the sea level and of its water becoming more salty with the access of waters from the Mediterranean Sea during the glacial era. This slime consists chiefly of numerous products of the putrefaction of organic matter and bacterial bodies. The process of formation has continued until even our time, as is proved by the presence of plenty of hydrogen sulphide on the bottom of the firth. From its slimy origin the mud of the firths, liman mud, unlike the turfy mud in western Europe, is extremely plastic, oily, thick and quick to oxidize.

A long time before Odessa was founded the local population used this mud for the healing of all kinds of chronic diseases. The treatment of patients with liman mud was recognized by the medical authorities in the fifties of the last century, from which time dates the construction of the first special clinics and hospitals in Odessa. The mud and rapa are used for general and local baths, applications and gynecologic tampons. The

following diseases are said to be affected by means of the liman mud: chronic and subacute arthritis, chronic gynecologic diseases and chronic and subacute inflammatory processes of the peripheral nervous system. The results of the treatment with liman mud are seen from the following items. Out of 1,000 arthritic patients 90 per cent were much improved, 40 per cent of them were able to move their joints, and 40 per cent of the patients suffering with all kinds of diseases of the peripheral nervous system got much better.

This is a matter of great importance because the number of arthritic patients is constantly increasing. According to the *Deutsche Krankenlassen Statistik* (Zimmer), the number of those patients is 82 times greater than that of tuberculous patients. The number of patients receiving their course of treatment on the Hadjibei and Koujalmik limans is increasing every year. In the summer of 1923 there were 1,500 patients and in 1930 there were 9,000.

Mortality in the Ukraine

The improvement in the living conditions of the Ukrainian people as a result of the October revolution led to a decrease in the mortality of the population and to the increase of childbirth. Mortality in 1928 was 36 per cent less than in 1913. This is particularly obvious in the two large industrial centers of this country. The mortality rate of 1927 as compared to that of 1910 is 57.3 per cent lower. As may be seen from the accompanying table, the child mortality has considerably decreased.

Infant Deaths in Each Thousand Births

		1910	1927	1927 Per centage in comparison with 1910
Town	Country			
Union of Soviet Socialist Republics	Moscow	24.1	13.5	49.8
	Charkoff	24.2	11.0	45.4
	Minsk	27.8	12.6	55.8
Warsaw	Poland	19.2	14.4	75.9
Riga	Latvia	17.9	14.1	80.3
Kowno	Lithuania	21.7	17.0	78.2

This table contains statistics from six large cities which were part of the former Russian empire. As may be seen, in towns of soviet Russia the child mortality has considerably diminished in comparison with the child mortality in towns of neighboring countries.

These items show that the Ukraine makes great progress as to the improvement of the health of its population. It must be also noted that there is a high birth rate in the soviet union, the natural increase of the population having risen 40.8 per cent from 1913 to 1928.

With the further growth and development of prophylactic and medical establishments, as well as with the rise of the population's cultural level, mortality in the Ukraine will diminish more and more.

Marriages

LAMAN T. MEEKS Indianapolis, to Miss Marie Olsen of Omaha, Neb., in Chicago, February 14.

THOMAS L. BENNETT, JR. to Miss Mildred Jackson, both of Florence Ala. February 17.

LOUIS PERLIN Richmond Va., to Miss Lillian Levin of Baltimore, February 15.

ARTHUR H. GRAHAM Opelika Ala., to Miss Henrie Elma Gholson, February 21.

R. L. ALVAREZ Galesville, Wis., to Miss Hazel Wanhass of Sparta, February 17.

Deaths

John Conrad Hemmeter * Baltimore University of Maryland School of Medicine Baltimore 1884 emeritus professor of clinical medicine at his alma mater, member and past president of the American Gastro-Enterological Association formerly on the staffs of the Bryn Mawr Hospital and the University Hospital, author of "The Special Pathology and Treatment of Diseases of the Digestive Organs," "Diseases of the Stomach," "Diseases of the Intestines," and others, aged 67 died, February 25, of carcinoma of the stomach

Henry Harrison Briggs * Asheville N C Yale University School of Medicine, New Haven, 1897 member of the American Academy of Ophthalmology and Oto-Laryngology American Laryngological, Rhinological and Otological Society American Ophthalmological Society and the American College of Surgeons, chief of staff at the Mission Hospital, aged 59 died, February 6 of heart disease, while at sea on the S S *Duchess of Bedford*

Charles Everett Stanley, Durham Conn, University of Pennsylvania School of Medicine Philadelphia 1876 member of the Connecticut State Medical Society and the New England Society of Psychiatry for many years on the staff of the Connecticut State Hospital, Middletown, aged 79, died in February

Francis Edward Victor Shore * Des Moines Iowa University of Michigan Medical School, Ann Arbor, 1886 member of the American College of Surgeons, past president of the Polk County Medical Society aged 67, died, February 9, in the Mercy Hospital, of arteriosclerosis

Melbourne Edward Armstrong, Bridgetown, N S Canada Medical Department of the University of the City of New York 1892 formerly county medical health officer for many years on the staff of the Annapolis County Asylum aged 64 died, January 1

Hugh Kidder, New York New York Homeopathic Medical College and Hospital, New York 1896 formerly instructor in clinical medicine at his alma mater, at one time on the staff of the Metropolitan Hospital, aged 61, died February 16, in the French Hospital

Charles John Colwell Oliver Hastings, Toronto Ont Canada, Victoria University Medical Department Coburg 1885 LKQCP Ireland 1886 past president of the American Public Health Association, medical health officer, aged 71 died, January 17

Roy Coutts, Toronto, Ont, Canada, University of Toronto Faculty of Medicine 1914 served during the World War on the staff of the Christie Street Hospital aged 46 was killed February 6, when the car in which he was driving was struck by a trolley car

William Blakeway Hanna * Mass Mich Hahnemann Medical College and Hospital Chicago, 1889, past president of the Ontonagon County Medical Society, formerly county coroner and bank president aged 67, died, February 15, of carcinoma

Ernest Harold De Muria * Brooklyn Columbia University College of Physicians and Surgeons New York 1920 aged 35 on the staffs of the Brooklyn Eye and Ear Hospital and the Brooklyn Hospital, where he died, February 19, of septicemia

William A Horton, Grayson, Ky Medical College of Ohio Cincinnati 1891 member of the Kentucky State Medical Association on the staff of the Stovall Memorial Hospital aged 64, died, February 19, of pneumonia following influenza

Paul Fitzgerald, Maplewood, N J, Medical Department of Columbia College New York 1894 associate medical director of the Prudential Life Insurance Company aged 62 was killed February 21, in Newark, when struck by a trolley car

John Christian Montgomery, Charlotte N C Medical Department of the University of the City of New York 1891 formerly professor of anesthetics North Carolina Medical College aged 62 died, February 18 of heart disease

Charles Colhoun, Rutherford, N J Medical Department of Columbia College New York 1890 member of the Medical Society of New Jersey for sixteen years member of the board of health of Rutherford aged 67 died in February

Richard B Henderson, Franklinton N C University of Maryland School of Medicine, Baltimore, 1884, member o.

the Medical Society of the State of North Carolina aged 73, died February 19 in the Duke Hospital Durham

Charles A R Campbell, San Antonio Texas Medical Department of the Tulane University of Louisiana New Orleans 1899 member of the State Medical Association of Texas aged 65 died February 20 of septicemia

Julius Jones Rockford Ark Vanderbilt University School of Medicine Nashville Tenn 1884 member of the Medical Association of the State of Alabama, aged 72, died, February 12 of endocarditis and nephritis

Preston Powell, Adair Iowa College of Physicians and Surgeons Chicago 1889 member of the Iowa State Medical Society aged 63 died in February in the Iowa Methodist Hospital Des Moines, of heart disease

Leon George Banton * Island Falls Maine Columbia University College of Physicians and Surgeons New York 1920 aged 36 died January 22 in the Aroostook Hospital, Houlton of ethyl chloride poisoning

Michael Frederick Brondstetter * Mount Pleasant Mich University of Michigan Medical School Ann Arbor, 1911, proprietor of a hospital bearing his name formerly county coroner aged 45, died February 14

Paul Hullhorst, Topeka Kan State University of Iowa College of Homeopathic Medicine Iowa City 1889 formerly lecturer on materia medica at his alma mater, aged 64, died February 5 in the Christ Hospital

Harry Mead Warner * Hempstead N Y University of Pennsylvania School of Medicine Philadelphia 1898 aged 57 died February 16 in India during a world cruise as the result of a fall from a train

Lewis Broadwell Brasher, Denver Gross Medical College Denver 1891 Civil War veteran aged 86 died January 26 in the Fitzsimons General Hospital of chronic pulmonary tuberculosis and myocarditis

James Rufus Gordon, Jamestown N C Baltimore Medical College 1891 formerly member of the state legislature and of the state board of health aged 73 died February 20 of cerebral hemorrhage

Mary S Sanderson, Amherst Mass University of Michigan Medical School Ann Arbor 1893 aged 67 physician in charge and owner of the Rangeview Sanitarium where she died, January 10

Charles Henry Weissberger * New York Medical Department of the University of the City of New York, 1885 on the staff of the Hospital for Joint Diseases aged 71, died February 16

John M Clarke, Burlington Vt University of Vermont College of Medicine Burlington 1873 aged 84 died January 17 in the Mary Fletcher Hospital, of pneumonia, following a fractured leg

Aime Noel Leblanc, Gardner Mass School of Medicine and Surgery of Montreal 1889 for twenty two years member of the board of health aged 66 died Nov 22, 1930 of heart disease

William Preston Copeland, Eufaula Ala Bellevue Hospital Medical College New York 1870 member of the Medical Association of the State of Alabama aged 85 died February 17

James Thomas Elliott, Denver, Ohio Medical University Columbus, 1897 member of the Colorado State Medical Society served during the World War aged 61, died February 21

Harvey Shoemaker * Philadelphia University of Pennsylvania School of Medicine Philadelphia 1886 chief of the medical service at the Landau Hospital aged 65 died February 2

Robert E B Bledsoe, McCamey Texas University of Texas School of Medicine 1898 member of the State Medical Association of Texas, aged 57 died February 1 of heart disease

Joseph Sutherland Graham, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1902, aged 50 died, January 6

Joseph Evan Hall @ Alexandria Ind Medical College of Indiana Indianapolis, 1881 aged 72 died February 16, of heart disease

Philip M Bell, Sherrodsville Ohio Toledo Medical College 1899 aged 70 died suddenly, February 13, of heart disease

Joseph Hyman Green, Toronto Ont Canada University of Toronto Faculty of Medicine 1925 aged 32 died Oct 17 1930

John C Lebrecht @ St Louis St Louis Medical College, 1882 aged 71 died February 23 of heart disease

Bureau of Investigation

W H Y

A Fraudulently Exploited Nostrum Debarred from the Mails

"W H Y" has been described by its exploiters as a "100 per cent pure, concentrated food beverage" It is marketed from Arizona Cal by the Bartlett Nu Products Corporation, a concern that was incorporated in 1920 under the laws of Arizona and having the following officers

C M BARTLETT President Treasurer and General Manager

A L McCULLOUGH Vice President

MRS G M BARTLETT Secretary

G M Bartlett claims to be the "discoverer" of the formula for W H Y the ingredients of which are said to be extracts of raisins, figs, walnuts, peanuts, barley, wheat and celery

Readers of this department of THE JOURNAL may remember that on November 24, 1928 there was published an abstract of

a Notice of Judgment against W H Y The government, at that time had declared that the claims on the trade package of W H Y, to the effect that the product aids digestion, assimilation and elimination and that it was a health sustaining food and that it was recommended by physicians and dietitians everywhere and that it was 'the cup of life and would feed your glands and give you strength' were false and fraudulent These charges were admitted and judgment of condemnation and forfeiture was entered

Since then, presumably, Mr Bartlett has been shrewd enough to remove from the trade package the fraudulent claims that brought him in contact with the food and drug

officials at Washington He has, however, apparently continued to make equally false and fraudulent claims in such of his advertising matter as does not go with the trade package As W H Y is sold through the United States mails, this has brought Mr Bartlett in conflict with another branch of the United States government—the postal authorities who have recently declared the exploitation of W H Y fraudulent and debarred it from the mails

The case of the Post Office Department against this humbug is described in the memorandum of the Hon Horace J Donnelly, Solicitor for the Post Office Department to the Postmaster General, in which Mr Donnelly recommended the issuance of a fraud order From this memorandum we learn that the Bartlett Nu Products Corporation is capitalized for five million dollars, that advertisements of the product have been carried in grocery catalogues on billboards and in circulars and folders sent through the mails 'sucker lists' have been furnished the concern by grocers and the individuals in these lists have been circularized the company has spent, on an average, \$20,000 a year advertising this nostrum

BY THIS IS

W. H. Y.

Saves Lives of Lost World Flyers

LOST for eleven days in the frozen wastes of one of the Aleutian Islands Alaska after their plane had crashed on a mountain hidden by fog Major Martin leader of the world flight expedition which left Clover Field March 1, and his mechanic sergeant Harvey astounded a whole world by winning the rush to Port Moller when even searching Timos and trappers had given them up for dead

MAJOR MARTIN'S first message after wreck in Alaska
To Washington
Our existence is due to CONCENTRATED FOOD and nerve

To His Wife
CONCENTRATED FOOD from a Los Angeles man saved our lives
It was W H Y—the perfectly balanced life sustaining concentrated food drink that all the World Flyers carried with them on their round the world history making trip

Some specifically fraudulent claims are taken up in detail, thus

Claim 1—That W H Y, when prepared ready to drink, furnished 460 calories to the teaspoonful

The nutrition experts for the Post Office Department showed that actually the product contained from 7 to 9 calories to the teaspoonful!

Claim 2—That W H Y contained the elements required for feeding the human body and that it was rich in vitamins

Government chemists found, as a matter of fact that W H Y contained no proteins or fats and therefore could not have any of the fat soluble vitamins, A and D. Furthermore, tests made in the vitamin laboratory of the Department of Agriculture failed to disclose the presence of vitamin B. Expert testimony was produced to show that the methods of preparing W H Y were such as to militate against the preservation of any vitamins that might have been present in the original ingredients

Claim 3—That children might be reared on W H Y alone

Mr Donnell's memorandum brought out the fact that it would be impossible to raise children on this preparation, that the stuff might cause severe diarrhea in many cases, and that it had no properly balanced food value

Claim 4—That W H Y was the only food recommended by the National Aeronautical Association as the official food for aviators

The government brought out that there is no such organization as the National Aeronautical Association!

Claim 5—That W H Y won the grand prize and gold medal award in a worldwide contest held at Limoges, France, in August 1929

The government proved that no medal or diploma was awarded to this concern at any fair or exhibition held at Limoges in 1929

Claim 6—That Baby Peggy, the motion-picture star lived six months on W H Y alone and was restored to perfect health by its use

The government produced statements from the parents of Baby Peggy showing that at no time was the product, W H Y, used by Baby Peggy

Claim 7—That the exploiters had arrangements with hospitals, sanitariums and doctors for distributing W H Y

The government brought out the fact that when asked for names to support this claim, Bartlett gave the names of Frances B Tyson M.D., of Leonia, N. J., and E. R. Lamberton M.D. of Los Angeles Cal. Mrs. Tyson is the sister of G. M. Bartlett and, according to the Solicitor's memorandum, had promised her brother to further the sale of the product, but admitted she did not know the formula and that, as a member of the medical profession, she would not allow her name to be used in any way in endorsing it. Dr. Lamberton, according to the Solicitor's report is not at the present time connected with the Bartlett concern but has admitted that he was, at one time, considering joining it

Claim 8—That Bartlett employed in connection with the business, two registered physicians

The names of the two physicians as given by Bartlett were Drs. Frances B. Tyson and E. R. Lamberton mentioned above neither of whom according to the evidence has been employed by Bartlett

As a result of this investigation, Solicitor Donnell declared the scheme one for obtaining money through the mails by means of false and fraudulent pretenses and recommended the issuance of a fraud order against the Bartlett Nu Products Corporation and its officers and agents, as such. The Postmaster General issued such an order February 24, 1931

Correspondence

ENDORSEMENT OF CREMO ANTISPIT ADVERTISING CAMPAIGN BY PUBLIC HEALTH WORKERS

To the Editor—You or your staff have undoubtedly seen my name and the names of some other public health officials in connection with the current advertising campaign of Cremo cigars.

I regret this occurrence very much as I am sure the other doctors also do.

When I endorsed their letter I thought that I was merely giving my opinion of the spit tipping practice and did not think they would exploit me in a nation wide publicity campaign. Had I known this was their intention I should not have endorsed the letter. I did not receive any remuneration of any kind for the endorsement. A young man living in town asked me to write an opinion of the spit tipping practice which I did. He then said that if I would give him a sheet of my paper with letterhead he would type it which he did. When he brought in the letter I very carelessly signed my name without carefully reading the contents.

I understand I am not trying to make an alibi as of course I have no one to blame but myself for my unthoughtfulness and hurry. Personally I shall be on guard in the future but I also would like to see others put on their guard which you can do through the medium of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

This kind of advertising is dirty to say the least and there are many in the advertising business who stand against the soliciting of testimonials in this manner.

O. FLINT CLOUGH, M.D., Poultney, Vt.

THE GALACTOSE TOLERANCE TEST

To the Editor—The discussion in THE JOURNAL (February 7, p. 459) between Dr. Blankenhorn of Cleveland and Dr. Loewy of London relative to the galactose tolerance test concerns a technique which we have studied for the past three years at the Jewish Hospital. Our conclusions regarding it are to appear in the *Archives of Internal Medicine*. I am in complete accord with Dr. Loewy, barring minor differences. I believe that the galactose tolerance test of Bauer stands today as our only positive means of identifying toxic hepatitis early, a condition whose identification becomes paramount in the painless (clinically obstructive) jaundice seen in persons past 30 or 40 years of age. Is it carcinoma of the head of the pancreas or silent stone in the duct or is it a so-called catarrhal jaundice? Should the patient be operated on early and spared the imminent danger of hemorrhage if operated on later? Can the patient be spared an operation in the presence of an undesirable symptom, jaundice? In helping to answer these questions the galactose tolerance test renders inestimable service. More than fifty cases of jaundice have now been studied and in no instance has the test been found wanting in separating the toxic or infectious jaundice from the obstructive and hemolytic types. One of the cases reported by us in the *Medical Clinics of North America* (January, p. 955) illustrates the points in question.

Regarding Dr. Blankenhorn's letter may I suggest that merely quoting textbooks that have failed to give due consideration to the test does not constitute damaging evidence. It is rather a reflection on the textbooks.

The article by Snell, Greene and Rowntree does not mention galactose, fructose having been used in their experiments. However, in a preceding article by Greene, Snell and Walters

they say "We shall summarize here the theoretical basis, technique and present status of the various tests employed in this work. Detailed reports will later be made with regard to the changes observed in a series of 800 cases, comprising various states." They do not even infer in their discussion of the carbohydrate tolerance tests whether galactose was tried but say that "glucose and galactose have proved unsatisfactory for clinical use." They too, have apparently come to a "literary" conclusion that the galactose tolerance test is worthless. This is certainly not the type of evidence to be offered.

The real difficulties that have beset the galactose tolerance test are twofold. First the physiology of the liver has not been properly considered in the evaluation of this test. The carbohydrate function of this organ is vital. Nature has accordingly provided both an adequate protection and reserve. The protective element is manifest in the extraordinary regenerative capacity of the liver cells.

The galactose test is concerned with the carbohydrate function of the liver. We cannot expect to find this function deranged in mild liver damage (adequate reserve) or in chronic liver damage (great regenerative power). These are the reasons why the galactose tolerance test is of no value in chronic liver disease and in jaundice not directly due to liver cell damage.

Should the liver cells be acutely and diffusely damaged we should expect and do find evidence of deranged carbohydrate function. Since these types of liver damage are nearly always accompanied by jaundice we have in this test an ideal method for identifying cases of toxic or infectious hepatitis. We have also been able to diagnose such cases of diffuse damage without jaundice by means of this test.

The second cause for the difficulties this test has encountered lies largely with the originator. Bruer first presented this test as a means of detecting cirrhosis of the liver and only later realized its significance in toxic hepatitis. Efforts have been made to utilize this test in chronic liver conditions, in which cases it has no reasonable place. In brief, a valuable test has been long left unused simply because we did not understand its limitations.

HARRY SHAY, M.D., Philadelphia

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

SKIN DISEASE CAUSED BY COLD

To the Editor—C. N., a truck driver aged 32 has complained for three weeks of tingling itching sensations in the skin of the feet, knees, buttocks, hands, ears and face when these parts become slightly cold. Relief is immediate and complete when the part is warmed. The annoyance keeps him continually confined to the house even in the mildest winter weather. He is perfectly comfortable as long as he remains in a heated room. He had a similar attack lasting throughout February and March three years ago. There is a history of arthritis in the lower part of the back five years ago otherwise he has been perfectly well all his life. Examination reveals that he is apparently healthy. The tonsils are slightly enlarged and there is an advanced pyorrhea of all the teeth. Dermatographism is pronounced. His bleeding time is normal but the coagulation time is prolonged. A tooth recently pulled bled so much that a packing was necessary several hours later to stop the hemorrhage. The hemoglobin and the red and white blood cell counts are normal; the differential count is practically normal and the urine is negative for albumin and casts. The affected parts do not show noticeable change during or after an attack. He has had 15 grains (1 Gm.) of calcium lactate three times a day for two weeks without any improvement. Could you suggest a diagnosis and treatment? Please omit name.

M.D. Iowa

ANSWER—The condition described appears to have certain relations to frost-bite and like it must be due to disturbance in the circulation. When the skin is pale and moist it is intolerant of chilling. As the patient under discussion is not anemic he probably has a tendency to angiospasm, possibly on a vagotonic basis in which dermatographism is also frequently evident. If this view of the underlying disturbance is

correct, atropine sulphate in doses of from 0.5 to 1 mg., taken one, two or three times a day ought to afford relief. The giving of calcium is also advisable, as calcium deficiency may be the cause of the vagotonia as well as of the prolonged coagulation time. To secure noticeable effect from calcium salts, however, they must be given in much larger doses than have been administered to the patient. The simplest and probably the best way is to prescribe calcium lactate, say 100 Gm., in bulk, and have the patient take a teaspoonful, stirred into a glassful of water, three times daily after meals. The peripheral circulation, especially of the hands and feet, may be improved by alternating hot and cold immersions, five seconds each for ten or fifteen times morning and evening. One commences with water as hot as can be borne and finishes with cold water and vigorous friction. For this friction one may use for prophylactic as well as for symptomatic relief an antipruritic with hyperemic and anhydrotic tendencies, salicylic acid (1 to 2 per cent) in alcohol which deserves first consideration for this purpose, as it is odorless and colorless. Addition of thymol and phenol (1 per cent of either or each) increases the hyperemic and antipruritic effect. The use of the lotion should be followed by liberal application of talcum powder.

TREATMENT OF IMPOTENCE

To the Editor—A man aged 30 married with a premarital history of no excesses, no gonorrhea, no syphilis and good health otherwise whose weight, blood pressure, urine, prostate and genitals are all apparently normal is able to effect erection but loses on intromission; i.e., he has premature ejaculations. There is no fatigue syndrome, no marital sexual excess and nothing of a neurasthenic or psychasthenic syndrome. What can you advise? If you publish please omit name, initials and city.

M.D. Kentucky

ANSWER—In many of these cases, although the prostate feels normal to the touch, a urethroscopic examination reveals a congestion of the prostatic urethra, especially in the region of the verumontanum. If such is the case it is important to relieve this congestion before resorting to stimulating treatment. For this purpose the patient should receive a deep urethral instillation of weak silver nitrate solution with the Bangs sound syringe every five days. One may begin with a 1:3,000 solution and gradually increase until 1:500 is reached.

In case congestion is not found, stimulating treatment should be commenced at once. The sinusoidal faradic current of moderate rapidity and as strong as the patient can bear without any pain is suggested. One cable is connected with a rectal electrode and the other with a wet-sponge electrode applied to the perineum and the current allowed to pass for about ten minutes. The prognosis is excellent in these cases.

SYMPTOMS OF CEREBRAL SOFTENING

To the Editor—Will you please give your opinion in regard to the following: Six weeks ago a woman in fair health aged 73 fell in her room on arising in the morning speechless, one side of her face drawn (left), her right arm and leg paralyzed completely and never unconscious. Speech returned a little after a few days but she cannot talk well. Her arm and leg are completely paralyzed. Her mind is bright and active. Please suggest the treatment and the probable prognosis. Kindly omit name and address.

N.D. New York

ANSWER—This patient probably has a cerebral softening due to a thrombosis of the lenticulostriate artery of the left side. The initial symptoms are usually much more severe than what one may expect from the actual destruction of the tissue. Therefore it is probable that some power in the extremities will return. There is no particular treatment that can be given. The outlook in patients of this advanced age is not very good.

ETIOLOGY OF ERUPTION IN WORKER WITH OIL

To the Editor—A man aged 27 who works in Superkool oil put out by D. J. Stewart of Chicago has developed a papulovesicular rash over all his fingers. I understand that this oil has about 8 per cent of sulphur and paraffin in it and that it is considered a high grade of oil. Could this dermatitis be due to the sulphur which I believe it is? Please send me any information on this subject. Please omit name.

M.D. Illinois

ANSWER—Sulphur dermatitis is dry and scaly. The common form of oil dermatitis is papulopustular, an acne. A vesicular eruption on the hands is nearly always either a dermatitis venenata or a ringworm. If the latter, the organism may be found in the roof of a vesicle, but is not always discoverable. Frequently, ringworm is found in the macerated epithelium between the toes. If this is an oil dermatitis it should clear up when the patient lies off, and recur when he returns to work.

ANAPHYLACTIC URTICARIA

To the Editor—A man aged 22, with negative family and personal history in good physical condition was afflicted with hives between the ages of 5 and 7 and never experienced a similar reaction until last spring, when he was traveling in the eastern part of the United States. He awoke one morning to find an unsightly welt in the right supra-orbital region. The only thing he had eaten for supper the night before was a candy bar. Two weeks later a similar reaction occurred. The intervals between the appearance of the welts became less until now there is seldom a day that the patient is without one or a combination of the following welts above the eyes, occipital region, arms, forearms, lower extremities (including plantar surfaces), abdominal skin brief (especially the thoracolumbar region), cheeks, lips and hands. The welts begin with a feeling of flushing on the particular area followed by a plateau-like arrangement with indurated edges which persists until the lesion begins to be absorbed. Absorption takes place in from four to twenty-four hours. Cripules of epinephrine and subcutaneous injection of epinephrine seem to hasten the absorption. The patient has been on various diets with high restriction on various proteins and carbohydrates with no influence on the condition. There is hardly a food that does not bring on the eruptions which vary in size from a few centimeters in diameter to ones covering the entire small of the back. Lettuce and sweet milk are the only things that do not affect him. The eruptions on the cheek are submucous and can be seen as a bubble-like lump under the mucosa. Can you suggest any procedure for determining the exacting cause, the diagnosis, the treatment and the prognosis? The condition is embarrassing to him since he is in a business which brings him into contact with many people daily.

M D Minnesota

ANSWER—This case evidently one of severe urticaria would have to be studied thoroughly before a diagnosis as to the cause could be made. It represents one of the most difficult types for diagnosis. Dangerous attacks can be relieved by epinephrine if given to the point of causing slight tremor of the hands. Solution of epinephrine hydrochloride in 0.25 cc doses ought to be used and this can be repeated every five minutes until relief or tremor of the hands is produced. An epinephrine reaction such as a heart pound can be stopped by putting a rubber tourniquet on the arm above the site of inoculation.

The outlook depends on the cause of the trouble. A case of this sort may clear up or continue with remissions for a number of years.

CAISSON DISEASE WITH MYELITIS

To the Editor—Dec 22 1930 at 2 p m a sand hog was decompressed too rapidly while leaving a caisson. The pressure was 41 pounds. I was called at 2 30 to attend him as he was suffering the bends of the abdomen and lower extremities. He was immediately placed in a hospital bed and recompression and decompression were done according to the New York State standards. After this treatment he was given camphorated tincture of opium and massage to give the relief which the bed did not give. At 6 a m the patient was resting quietly in bed. At 8 a m he complained of inability to move the lower extremities but sensation was present. He was immediately replaced in the hospital bed, recompression was done to 42 pounds and for one hour massage of the lower extremities and back was administered. During this time the patient did not experience any relief. He was decompressed in one hour and placed in a hospital bed. He is unable to urinate and defecate. Sensation is present the knee jerks are hyperactive, ankle clonus is present and the Babinski reflex is positive. I desire information regarding treatment other than catheterization, enemas and guarding against bedsores. I will appreciate an early answer kindly omit name.

M D Texas

ANSWER—This promises to be a typical case of so called caisson myelitis which really is not a myelitis as it is not truly inflammatory. In this case the nitrogen bubbles that escaped from the small vessels in the cord during the rapid decompression had already done structural damage to the cord fabric before they returned to the blood during the recompression. Small areas of necrosis, perhaps with small hemorrhages, remain and will gradually be converted to fibrous tissue. In this case it appears that the pyramidal tracts have suffered the most. It is no use to do any more recompression or to apply aggressive form of treatment of any kind. The main thing is to take good care of the bladder and skin, which may mean keeping the patient on a water bed if the paralysis of the legs is complete. Small doses of iodide of potash will be in order.

PROGNOSIS IN PERNICIOUS ANEMIA—SPINAL ANESTHESIA

To the Editor—1 What is the probable duration of life in patients suffering with pernicious anemia apparently successfully treated by modern methods? What I want to find out is the potency of the treatment over a number of years for example. 2 What solution do you recommend for spinal anesthesia as on the whole most efficient and safe? Please omit name and address.

M D Massachusetts

ANSWER—1 The evidence is that patients suffering from pernicious anemia who are treated with an adequate amount of liver or a potent substitute remain indefinitely in a satisfactory state of health. The problem is not to treat the patients with

liver but to treat them with enough liver or a potent substitute. It must be recognized that such complications as infection damage to the cardiovascular system and severe injury to the liver are causes of death and, when they arise in pernicious anemia, often handicap the beneficial effect of modern treatment.

2 A solution of crystals of procaine hydrochloride dissolved in spinal fluid has been proved to be on the whole the most efficient and safest agent for spinal anesthesia. This agent usually produces anesthesia whereas other local anesthetic agents fail more than occasionally. On the other hand anesthesia may not last as long with procaine hydrochloride solution as with some other agents.

SUPRARENAL EXTRACT IN EXHAUSTIVE STATES

To the Editor—In discussing a paper on the Exhaustive States given at the annual session of the American Medical Association in 1929 Dr N S Davis stated that a suprarenal extract which is effective when given orally had recently been developed at the University of Chicago. Do you know whether this product is on the market and if so where it can be obtained? Please omit name.

M D New York

ANSWER—The preparation is still in the experimental stage and is not available on the market. It is a preparation of the suprarenal cortex that is epinephrine-free. When given in considerable amounts it is effective orally, but it has a much more uniform action when given hypodermically. This preparation in certain cases increases the mechanical efficiency, raises the basal metabolic rate, and increases the combustion of sugar.

TREATMENT OF MIGRAINE

To the Editor—A woman aged 52 menstruating until three years ago has paroxysmal left-sided headaches. The headaches began about fifteen years ago and seemed to appear about the menstrual periods lasting only fifteen or twenty minutes but occurring several times daily. They are of a throbbing type located in the temporal parietal regions and in the past few years have extended into the occipital and postoccipital regions. Position seems to have little or no effect during the paroxysms. During the past five years she has had the headaches every day lasting fifteen or twenty minutes and returning every three to four hours. There is no particular cardiovascular weakness, the blood pressure is 122 systolic and 72 diastolic. The urine and blood Wassermann examinations were negative. She has had no diseases since childhood when she had malaria. There seems to be no pallor of the face during an attack nor have I been able to distinguish any change in the fundus of the eyes. Yet there is some loss of vision of the left eye. The eyes have been examined by a competent ophthalmologist. I have given her extract of hyoseyamus, phenobarbital and amidopyrine which have given some relief. She sleeps much better without paroxysms at night but the first attack is about 6 o'clock every morning. If you have some suggestions on this case I would appreciate them.

J WENDALL MERCER M D Cherokee Okla

ANSWER—If there are no signs of cerebral arteriosclerosis, the type of headache described with such a long chronicity may well be considered as migrainous, but the cause of the loss of vision was not stated. It is well to keep check on the optic disks at regular intervals on a patient of this age who has almost continuous headaches. Fluid extract of cannabis in increasing drop doses sometimes is helpful in the treatment of migraine provided the drug is increased to just below the dose necessary to produce the first signs of intoxication.

SCARLET FEVER STREPTOCOCCUS

To the Editor—Has the micro-organism of scarlet fever been isolated? If so what is it? Is Dick's conclusion as to the cause of scarlet fever generally admitted by the profession? If so can throat swabs and cultures determine who is and who is not a scarlet fever germ carrier? Please omit name.

M D Massachusetts

ANSWER—It appears to be generally accepted that scarlet fever is caused by a form of streptococcus. George F Dick and Gladys H Dick have demonstrated definitively that scarlet fever is caused by a streptococcus which produces a specific toxin that susceptibility to scarlet fever can be determined by the presence or absence of reaction to this toxin when injected intradermally. That susceptible persons can be protected against scarlet fever by injections of this toxin and that a useful antiserum against scarlet fever can be obtained by immunizing horses with the toxin. On account of the difficulty of recognizing the scarlet fever streptococcus either by its form or by its growth on artificial cultures it is not practically possible at this time to determine by swabs and cultures whether a given person is a scarlet fever carrier. The scarlet fever streptococcus can be recognized by its power to produce a specific toxin and by certain immune reactions but these methods are rather too complicated to be applicable in practical work as the matter stands at present.

VASOMOTOR PHENOMENA WITH URTICARIA

To the Editor—I have recently seen a condition in a child of which I am unable to find mentioned in any of my textbooks. This little girl aged 5½ years white has recently passed through an attack of influenza. There was a bronchitis acute coryza and unilateral conjunctivitis with subconjunctival hemorrhage. She is at this time convalescing from these conditions and has no fever. Two days ago there began to appear in the infra orbital region in erythrodermia which was about the size of a fifty cent piece (30 mm in diameter) and which spread out fan shaped in the direction of the jaw. The redness was not attended by subjective symptoms and persisted for about five minutes when it suddenly disappeared. About half an hour later the same condition appeared on the opposite cheek and disappeared in a like manner. This would seem to be some vasomotor disturbance and I am interested from purely an academic standpoint to know whether there is any explanation of the condition. Please omit name.

M D Virginia

ANSWER—The vasomotor phenomenon described might have been caused by any of the forms of irritation that cause other vasomotor disturbances like urticaria. Did the child receive any serum injection during the illness or recently? If not drugs, intestinal toxins or reflexes from internal organs might be to blame. The depression following influenza may have lowered the threshold to irritation.

LACTICACID FLORA OF VAGINA

To the Editor—Recently I noticed in a slide and culture from a normal vagina the presence of a type of bacilli that have long been puzzling me. Although I have consulted at least a dozen good reference I have as yet been unable to discover just what it is. The bacilli are approximately 6 microns long by 1 micron wide. They have a tendency to form chains of two to four bacilli in culture. There was an abundant growth on both nutrient agar and telluric agar. (In your suggestion from the few facts anything they could be I undoubtedly think them to be saprophytes as the same pure inoculated intracritically with a pure culture five days ago do not show signs of illness. Two on motility were negative for pathologic appearances. The bacilli were recovered from both of them at the autopsy.)

D BERNETT LAUDER Oakland Calif

ANSWER—It is difficult to tell from the description exactly what the organism in question is for there are a large number of different types of bacilli in the vagina. One author lists sixteen main groups of vaginal bacilli some of which are divided into smaller classes. An extensive article on the morphology and technique of the vaginal flora was contributed by R. Schommon to J. Hilban and L. Seitz's *Biologie und Pathologie des Weibes*, Berlin Urban and Schwarzenberg, 3 1156 1924.

HEREDITARY AND CONGENITAL DISEASE

To the Editor—Will you please explain the difference between hereditary and congenital diseases. Can you classify syphilis as hereditary? My understanding was that hemophilia otosclerosis and insanity were the only true hereditary diseases. One of course may be born with syphilis but to call it hereditary is hard to understand. Why not congenital only if it exists at birth or is acquired later on in life? Syphilis is not transmitted as a constitutional quality from parent to child—you have or have not the disease. Why the three diseases mentioned are hereditary is easy to understand—why others are classed so is hard to understand.

M D Wisconsin

ANSWER—The terms hereditary and congenital are often used as synonymous in speaking of disease. This leads to confusion. Strictly speaking a disease of any sort is congenital if it is present at birth even if known to be due to prenatal infection or to unfavorable uterine environment. Only those diseases are hereditary which are due to a condition different from the normal in the actual make up of the hereditary substance in the germ cell egg or sperm.

In this sense syphilis is congenital but not hereditary. What is inherited in many diseases is relative susceptibility or immunity to a disease not the disease itself.

ACTION AND USES OF SODIUM GLYCEROPHOSPHATE

To the Editor—Will you please inform me as to the maximum amount of sodium glycerophosphate that might be taken in one dose and also the maximum amount that could be taken daily without any harmful effect. Is this drug a toxicant in any dosage and if so in what way is it manifest? I realize its practical value as a drug is nil. Please omit name.

M D Michigan

ANSWER—Sodium glycerophosphate has been used in doses up to 10 Gm (150 grains). Information on its toxicology seems to be lacking but there is no doubt that in large doses and concentrated solution it will act as an irritant poison by reason of its salt action. As our correspondent points out the glycerophosphate propaganda was based on false premises. The glycerophosphate radical has no therapeutic advantage over the ordinary and more economical phosphate.

CLINICAL CASE STUDIES AS INSTRUMENTS IN THE TEACHING OF PUBLIC HEALTH

H A HISCOCK, CH

Associate Professor of Public Health Yale University School of Medicine
NEW HAVEN CONN

Increasing recognition of prevention as the keynote in the practice of modern medicine has stimulated interest in the nature of public health instruction in medical schools. Important advances in this field of education have been made in recent years, but there is considerable variation in different institutions in the scope of courses and in the methods of instruction. In the training of medical students at Yale public health is considered as a fundamental point of view that should permeate the daily activities of the individual practitioner and make him an active factor in the community health program.

The department of public health at Yale is constituted as one of the basic divisions of the school of medicine. The teaching of public health is correlated through a committee on preventive medicine, with instruction given in the first three years by other departments of the medical school which have representatives on this standing committee. The attitude of the medical students has changed over a period of years, as a result of a new attitude on the part of the whole faculty of the school. It is fair to say that every department from pathology to pediatrics is teaching preventive medicine.

The department of public health gives a course in principles of public health in the first half of the second clinical year that summarizes the main problems involved. This course consists of lectures discussions in small groups and field work. The course includes facts about water supply, waste disposal and ventilation that the average physician should know but its chief aim is to review all the student has learned in the three years of his relations to the community and to show him the part that he as a physician must be prepared to play in campaigns concerning child hygiene, tuberculosis venereal disease and mental hygiene.

Practical field work and demonstrations to illustrate the underlying principles of public health are essential features of the instruction of medical students. Until two years ago field work at Yale as in many other medical schools included a health survey of a city or town. The value of sanitary surveys depends largely on the care given to the collection and analysis of data. If properly supervised and supported they may benefit

communities and students alike, but if performed in a haphazard or perfunctory manner, they are both time consuming, and worthless from an educational standpoint

ORIGIN AND PURPOSE OF CASE STUDIES

The medical student enters the wards in his first clinical year and is beginning his dispensary work in his second clinical year. He finds this work more fascinating than making a health survey of the usual type, which he is inclined to regard as outside his realm and so much time taken from what he is likely at this period to consider his real medical activities. The clinical case study plan herein described was devised to take the place of the conventional health survey previously required. Through this means, the student approaches the community health program from the inside, through a personal medical contact with the individual case, working out from this concrete experience rather than from the outside abstract approach through governmental and voluntary organizations. Attention is therefore primarily devoted to the importance of considering the relationships of a medical case to the home, the family and the community. Particular emphasis is given to the public health and social machinery that is available or that ought to be available for the prevention and alleviation of disease.

For two years, clinical departments in the medical school have cooperated with public health in the organization of a series of studies, by students in the second clinical year, of selected cases from the dispensary and hospital services. The purpose of these studies is to give the medical student a clearer conception of the varied factors underlying the immediate acute condition of illness or incapacity, seen in the dispensary or hospital, and especially to provide opportunity to consider the causes operative in a case and the methods by which the illness might have been prevented. Such a plan includes a study of community resources for handling various types of problems, medical, nursing, clinical, social service and the like, all parts of the broad problem of public health.

SELECTION OF CASES

The following types of cases were selected

Amebic dysentery
Gonorrhea
Meningococcus meningitis
Pneumonia
Rheumatic fever
Scarlet fever
Syphilis, including congenital
Tuberculosis, adult and childhood
Whooping cough
Industrial accidents and diseases
Heart disease, adult and childhood
Orthopedic cases
Special surgical cases
Prenatal and obstetric cases
Mental hygiene cases

The student was first given an opportunity to express his preference as to the type of case he would follow. Some had seen patients in the dispensary or hospital in which they had become interested. The cases so suggested were discussed with the physician in charge of the clinic to be sure that this type of study on a given case was practical. Ultimately each student was assigned one case for follow up.

PROCEDURE

After the cases were assigned the students conferred with the physician in charge of the clinic concerned and went over the case record in the dispensary or hospital noting at that time what service the patient had received and what other community agencies were involved.

To gain a first hand impression of home and family conditions from one to five home visits were made on each family. The families in most cases were responsive and gave the students

more information regarding family histories and problems than had heretofore been noted. Information was obtained regarding living and working conditions, the size of the income in relation to the size of the family, histories of previous illnesses in the family, and agencies known by the family as having rendered service.

After the home visit, students interviewed heads of the nursing, mental hygiene or social service agencies carrying the cases to obtain their points of view. When the visiting nurse association was concerned the nurse of the district in charge of the patient was interviewed. The organization and work of the most important agencies were studied. The student considered the problem of prevention, what legislation existed or should have existed that could minimize the likelihood of the disease or accident in question and what steps the board of health, the employer, the dispensary, the visiting nurse association or the mental hygiene society had taken or might have taken to prevent it. In other words he was asked to work from the condition of the individual disease back to its underlying causes and out to the entire community machinery for prevention and treatment as applied to the disease in question.

A detailed report of the case was finally prepared for presentation in class conference. As a guide in the preliminary study of the problem each student was given the following outline of factors to be considered, but emphasis was placed on the importance of using initiative in working up the case.

FACTORS TO CONSIDER IN THE FOLLOW UP OF CLINICAL CASES

I The patient

- (a) Description of individual and of case
- (b) Immediate cause of dispensary visit
- (c) Underlying causes discovered either in the dispensary or on home visit which have an important bearing on the production of the medical or surgical complaint
- (d) Other related factors in present or past social history
- (e) Response to advice and treatment in dispensary or hospital. If response is not good, why? What are the underlying causes?
- (f) Has medical advice been sought previously outside the clinic? From physician? Other? Use of patent medicines?

II The family

- (a) Description and social history. Social tendencies of mother and father
- (b) Special health, medical or social problems
- (c) Contacts with dispensary or hospitals
- (d) Factors related to case study—financial status, etc.

III The home and surroundings

- (a) Description, general appearance, light, heat, yard, mill supply, food supply, surroundings
- (b) Reasons for present home circumstances

IV The community

- (a) Social or health agencies concerned over period of years
- (b) Services rendered—adequacy
- (c) Attitude of family toward agencies
- (d) Possibilities of other services needed
- (e) Has the community handled the problem properly? Are there any suggestions for a more scientific treatment of this case from a medical or social point of view?

V Summary

- (a) How could the medical, mental or surgical condition have been prevented?
- (b) How can conditions be improved?
- (c) Specific recommendations regarding this case
- (d) Specific recommendations regarding this type of follow up study in the future

VI List of persons and agencies interviewed regarding the case

PRESENTATION OF REPORTS

The series of reports was arranged so that similar problems were presented at the same period. Ten fifty minute period,

previously used for group conferences and field trips were set aside for this purpose. The city health officer, the director of the visiting nurse association and the director of the dispensary were invited to attend all the sessions. When tuberculosis cases were reported the head of the tuberculosis clinic and hospital service, the director of the city tuberculosis bureau and representatives of community social agencies were also present. In the same manner representatives of clinics and of nursing and social agencies were invited to be present at the sessions when cases in their fields were presented in order to participate in the discussion, to supplement the reports, to answer questions and to consider the problems from the standpoint of what might have been done as well as what might be the developments of the future. The members of the class participated actively in the discussion. The executive secretary of the community chest was helpful on special occasions as a social service consultant since he is thoroughly acquainted with local and state conditions and with the broad problem of social service.

In the future it is planned to clear each case at the outset through the social service exchange and during the three months in the fall and winter when the cases are being followed to receive reports of new contacts with each family is additional aids to the students. This procedure is considered desirable in spite of the fact that the dispensary records show the agencies at work on the case at the time the study is undertaken.

Among the questions usually asked after a case was reported were the following: How could this condition have been prevented? After the condition developed, were the proper steps taken for its detection and amelioration? What can be done about the situation at present? How far are the community resources adequate to meet situations of this kind?

Many of the cases raised legal, social, mental, medical, nursing and public health questions. The students studied their cases intelligently and industriously and their reports were carefully prepared. In fact some of the reports have formed the bases of clinical lectures and may be used for community case conferences by social agencies.

VALUE OF CASE STUDIES

The students become impressed with the fact that frequently the condition of a patient who comes for medical advice or treatment is only an end result of some earlier symptom or condition. In many cases the condition that prompted a patient to come to the clinic is not nearly as serious as some other problem of the patient or his family that may be disclosed subsequently. Often the problem calls for more than medical treatment, nursing care or social service, requiring a combination of all. A new type of technique is necessary which reaches even beyond medical social service.

In the children's tuberculosis clinic of the dispensary there are found children with tuberculosis from outlying towns in which a milk supply is suspected. The local health officer must be approached, the dairy inspected, the herd tuberculin tested. Or in a family in which there is an adult with tuberculosis, contacts may be found who have not been examined and in whom additional stimulus is necessary to bring about the necessary visits to the clinic. In visiting a medical case one may find several children who show marked signs of rickets or malnutrition or some other defect and the parents are urged to bring the children to the clinic. The student may arrange to meet the family at the time of the next visit to the clinic and thereby establish closer working relationships and better understanding.

Certain diseases or disabilities may suggest association with abnormal living or working conditions that need an investigation into housing problems or industrial hazards. Others lead directly back to epidemiologic factors that might have been controlled by more adequate community machinery or closer working relationships. In the field of mental hygiene problems of the courts and of various social agencies in dealing with

emotional and psychologic factors are revealed. Other studies bring one face to face with economic and social problems, and with problems of eugenics that need careful consideration.

These studies have proved of direct value to the clinics, to the students and to the patients. Fundamental prevention was emphasized and vital contact was made between the patient in the dispensary or hospital and the preventive and ameliorative machinery of the community. At the conclusion of an annual series of case reports the students have become familiar with the community health and welfare resources and with problems of human relations. Through the breadth of view and the vital human sympathies aroused, it is believed that the students will approach patients in their private practice more constructively and humanely and that they will participate far more effectively and sympathetically in the public health programs of the community as a result of this experience.

310 Cedar Street

Minnesota October Examination

Dr E. J. Engberg, secretary of the Board of Medical Examiners of Minnesota, reports the oral, written and practical examination held at Minneapolis, Oct. 21-23, 1930. The examination covered 11 subjects and included 60 questions. An average of 75 per cent was required to pass. Forty-seven candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Iowa University School of Medicine	(1930)	94.5	
Northwestern University Medical School	(1930)	90.4	92.1
Rush Medical College	(1930)		88.3
University of Illinois College of Medicine	(1930)		90.4
Indiana University School of Medicine	(1927)		89.6
State University of Iowa College of Medicine	(1928)		91.5
University of Louisville School of Medicine	(1929)		89.1
University of Maryland School of Medicine	(1929)		92.1
Harvard University Medical School	(1929)		97
University of Michigan Medical School	(1928)		91.3
University of Minnesota Medical School	(1928)		89.2
(1930)	82.6 * 84.5 * 86.6 * 86.5 * 86.5 * 87.2 * 87.3 * 87.5 * 88.2 * 88.3 * 88.6 * 89.5 * 89.5 * 90.0 * 90.3 * 90.3 * 90.4 * 90.6 * 93.5		
Washington University School of Medicine	(1929)		96.7
Columbia University College of Phys. and Surg.	(1928)		90.7
University of Cincinnati College of Medicine	(1929)		86
Western Reserve University School of Medicine	(1929)		90.5
University of Oregon Medical School	(1929)		93.3
Jefferson Medical College	(1929)		97.3
University of Pennsylvania School of Med.	(1928)	87.6	(1929) 89.1
University of Virginia Department of Medicine	(1928)		91

Dr Engberg also reports 6 physicians licensed through reciprocity with other states and 5 by the endorsement of credentials at the same meeting. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Stanford University School of Medicine	(1930)		California
Rush Medical College	(1928)		Illinois
University of Louisville School of Medicine	(1929)		Kentucky
St. Louis University School of Medicine	(1928)		Michigan
Creighton University School of Medicine	(1929)		Nebraska
University of Wisconsin Medical School	(1928)		Wisconsin

College	ENDORSEMENT OF CREDENTIALS	Year Grad	Endorsement of

University of Michigan Medical School	(1928)		N. B. M. Ex.
University of Minnesota Medical School	(1929)		N. B. M. Ex.
Columbia University College of Phys. and Surg.	(1926)		N. B. M. Ex.

* These applicants have received their M.B. degrees and will receive their M.D. degrees on completion of one year's internship in a hospital.

Kansas December Examination

Dr C. H. Ewing, secretary of the Kansas State Board of Medical Registration and Examination, reports the written examination held at Topeka, Dec. 9-10, 1930. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Thirteen candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Howard University School of Medicine	(1930)	86.8	87.1
Rush Medical College	(1928)	93.0	93.1
University of Kansas School of Medicine	(1930)	81.4	91.7
Kansas City Hahnemann Medical College	(1912)		83.8
Creighton University School of Medicine	(1930)	90.2	90.3
University of Oklahoma School of Medicine	(1930)		91.6
			92.4

Dr Fung also reports 18 physicians licensed through reciprocity with other states at the same meeting. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Colorado School of Medicine	(1929)	Colorado	
American Medical Missionary College	(1905)	Nebraska	
Rush Medical College	(1924)	California	
State University of Iowa College of Medicine	(1926)	Iowa

Book Notices

THE PATHOLOGY OF INTERNAL DISEASES. By William Boyd M.D. MRCI FRSC, Professor of Pathology in the University of Manitoba. Cloth Price \$10. 1 p. 888 with 296 illustrations. Philadelphia Lea & Febiger 1931.

This is a companion piece to the author's Surgical Pathology. The two volumes look alike, although published by different firms. A few borderline diseases are described in both volumes, an overlapping that is probably unavoidable and perhaps desirable. Many of the illustrations in Surgical Pathology are also in this new work. The author states that he has not confined himself to the strict limits of morbid anatomy but has allowed himself to wander rather freely in the realms of pathologic physiology. This attempt to correlate symptoms with lesions is the most distinctive feature of the treatise and receives due emphasis in the charming foreword by Barker accompanying the preface. It is altogether natural to find this later work written in a more agreeable style than the earlier one. There is something of lure and camaraderie in the way the reader is led on by such expressions as 'we have just seen,' 'when we consider,' and 'these facts justify us.' On the other hand, it is seen that, "it appears," it becomes evident' and numerous other similar beginnings are tedious. In one case on which I performed an autopsy' (p. 698) and the 'case which was typed 301 times' (p. 339) are disturbing, to say the least. The beaten path is left for a frolic now and then when we accompany him steering a careful course between the Scylla of an unwarranted particularization and the Charybdis of a speculative nihilism' (p. 795). The Scylla and Charybdis of lymphoid tissues are also dangers for the tubercle bacillus (p. 197). Should it succeed in passing these, 'it sets out upon an Odyssey which may carry it far and wide throughout the body'.

On the whole, Professor Boyd's assurance has endowed his phraseology with literary power and some brilliance. His descriptions of disease impart a feeling of security and confidence in the information set forth. He says, for example, in discussing tabes dorsalis, 'my information is not first hand' and in another place, 'it would be possible to write at great length on the subject of eclampsia but nothing would be gained thereby.' Many will endorse his opinion that the term 'nephrosis' is responsible for much confusion and loose thinking' and this will apply equally well to the recently proposed 'myocardosis' if its use becomes general. The familiar 'fibrosis' lacks precise significance and it is safe to assume that few will be able to anticipate from the heading 'Hydrohepatosis' on page 336 the content of the paragraph that follows. It is refreshing to find, introducing the discussion of the reticulo-endothelial system, that it is invoked to explain all kinds of emigmas and has been considerably overworked in this respect. Frequently one encounters sentences fairly gorgeous with significance. In discussing certain cells in the spleen they are 'entrapped in the pathless forest of the pulp' Agnir (p. 442). There is no more perplexing subject in pathology none more baffling and tantalizing than the relationship between arterial and renal disease.

The plan is that which is generally followed in textbooks on special pathology or the morbid anatomy of the viscera starting with the heart and blood vessels and ending with the central nervous system. The first chapter is twice as long as any of the others except that on the lungs. Diseases of the skin, joints, genital and lower urinary organs, apparently all without the

scope of internal diseases are omitted, those of the bone marrow have a short chapter. The rather even level of excellence makes it difficult to choose portions for especial commendation. However among other subjects diseases of the blood and of the thyroid gland and pulmonary tuberculosis are discussed in an admirable and forceful manner, and with thoughtful attention to recent developments. The pages (427-437) devoted to the relation of symptoms of Bright's disease to its morbid anatomy may be recommended as a sample should one be desired, to bring about prolonged examination of the entire volume. Throughout the book there is evidence of wide acquaintance with medical history and important contributions to knowledge of disease. Requisite compactness has been attained by limiting the text to essentials and wise selection of references for the short bibliographies at the end of the chapters. The author is to be congratulated on his success in linking up the pathology so commonly segregated to instructors and student days with the routine practice of medicine.

ANALYTICAL REVIEW OF REPORTS FROM PASTEUR INSTITUTES ON THE RESULTS OF ANTI-RABIES TREATMENT. By Lt Col A. G. McKendrick F.R.S. Director of the Laboratory of the Royal College of Physicians. Edinburgh. Health Organization League of Nations III. Health 1930 III 2 C II 844. Paper. Pp. 158. Geneva. League of Nations 1930.

The International Rabies Conference, which was convened by the Health Organization of the League of Nations in 1927 adopted the resolution asking antirabies institutes of all countries to submit the results of antirabies treatment on a uniform plan. Statistics of 31,636 persons treated at 31 antirabies institutes have been analyzed. They are subdivided into two groups the European and the non European with the results that the non European group appears to be at a higher state of risk than the European and that there is no indication in favor of any one of the many methods of treatment used. Particularly there is no indication favoring the use of live rather than killed vaccines. The variation in the death rates among the various European institutes is not greater than would be expected as the result of chance variation. The same is true of the non European group. A comparison of the death rates for the two groups however, shows that the incidence of death due to rabies is higher in the non European group. The data are based on a small proportion of all the institutes of the world. It is expected that more definite conclusions can be reached as the scope of this analysis increases.

PHARMACEUTICAL MATHEMATICS. By Edward Spence Ph.C. B.S. Professor of Pharmacy and Dean of the School of Pharmacy, Western Reserve University. Cloth Price \$1.75. Pp. 126. New York. McGraw Hill Book Company Inc. 1930.

This little book covers the ordinary problems dealt with in pharmacy. Even physicians who may be rusty on matters of specific gravity, on percentage solutions and on the uses of tables will find items of help. The book is not in any sense profound in fact the term mathematics is almost too dignified. It is essentially an application of ordinary arithmetic to pharmaceutical problems.

THÉRAPEUTIQUE MÉDICALE. II. ALIMENTS MÉDICAMENTEUX. Par MM. M. Loeper, Marcel Labbe et al. 149 p. Price 45 francs. 1 p. 328 with illustrations. Paris. Masson & Cie 1930.

This French book on the medicinal uses of foods deserves more than passing notice as it contains quite an array of ideas and data not generally found in the literature in this country. Thus, Loeper in an introductory chapter proposes the term vitines for what we call vitamins because he believes that our present knowledge of these bodies requires their subdivision into two classes the fat soluble bodies, which should be called vitasterines embracing A, D and E and the water soluble or true vitamins B, C the antipellagrous body and at least two 'cellular nutrition' bodies. Richet in a chapter on zomotherapy (from the Greek *zomos* bouillon) relates his observations on the therapeutic value of raw meat juice on tuberculous dogs and human beings. He has elaborated a powder obtained by drying meat juice at a low temperature which produced in his hand remarkable effects in early cases of human tuberculosis when taken in sufficient quantity. Doses of from 80 to 120 Gm a day are generally well borne excepting in cases of peritoneal and intestinal tuberculosis in which diarrhea is liable to interfere. He proposes the unfortunate name *zomine* for this powder,

objectionable because the ending me should be reserved for pure active principles. Maurice Renaud deprecates the prescribing of milk *en bloc*. One should vary the composition according to the requirements of the patient and not give the same milk preparation to a baby, a senile person, a dyspeptic and a urticant patient. He brings out particularly well the climatic value of whey. The chapters on the nutritive and therapeutic value of wine, by M. Loeper and J. Alquier, and of beer, by Rioul Lecoq, will cheer the heart of the professional wet. It is necessary to pass, for lack of space, masterly lectures on vegetable 'cures' by Henri Labbe and on fruit 'cures' by Henri Jecle, but especial attention should be given to the chapter on the therapeutics of sugar, by Noel Fiesinger, who advocates sugar as a medicament in hyperchlorhydria and gastric ulcer on the basis of the fact that it depresses gastric secretion. He also maintains that in certain persons highly sugared foods are retained and digested when in others this would be impossible and that for this reason sugar is an important remedy in the treatment of vomiting. He quotes Looper and Marshall as ascribing an antianaphylactic effect to sugar on the basis of the observation in a number of cases in which fish bouillon produced an eruption that could be prevented by the addition of sugar or in which sugared egg was tolerated by a person anaphylactically intolerant of egg. They ascribe this effect to the leukocytosis produced by sugar. A sedative action on the opening of the ampulla of Vater is also claimed for sugar so that egg with sugar may not produce the biliary colic that would be caused by egg without it. He admits, however, that there are dyspeptic patients who cannot take sugar without a hyperacidity reaction, which he considers due to an abnormal sensitivity of the gastric mucosa. The necessity for the availability of sugar in immunity reactions leads him to the statement that in infectious diseases and intoxication the hydrocarbons form the basis of the therapeutic edifice. Good chapters on sea salt, cod liver oil and irradiated foods close this inspiring book.

THE TREATMENT OF HUMAN TRYPA NOSOMIASIS WITH TRYPARSAMIDE. A CRITICAL REVIEW. By Louise Pearce, M.D. Monographs of the Rockefeller Institute for Medical Research No. 2. Paper. Price \$2. 1p. 339. New York: Rockefeller Institute for Medical Research, 1930.

Here is a thorough digest of the treatment of human trypanosomiasis with tryparsamide. The author was closely identified with this work long before the introduction of tryparsamide to the medical profession. The work with this preparation has been done in a highly scientific manner. This monograph attests to the care with which Dr. Pearce has pursued her studies. Eight years has elapsed since the tryparsamide treatment of African sleeping sickness was instituted in the Belgian Congo. As the author points out, in the intervening years the use of the drug has constantly increased throughout tropical Africa where trypanosomiasis occurs, and considerable literature has accumulated on the subject. The monograph includes a review of the available records of cases that bear on tryparsamide therapy, the total number of cases considered being 1,848. From her critical analysis of the data Dr. Pearce concludes that tryparsamide is an efficacious drug for the treatment of trypanosomiasis caused by *Trypanosoma gambiense* and that it is to be recommended for general use under the conditions of both lazaret and field administration. For those interested in the treatment of human trypanosomiasis, the monograph will be found not only of interest but of real service.

PIELOGRAFIA ASCENDENTE E PIELOGRAFIA DISCENDENTE CON SPECIALE RIGUARDO ALLA NEFROPILOURETTEROPILOGRAFIA PER VIA ENDOVENOSA. Di Prof. Carlo Ravasini. Primario del Reparto Urologico (C. Nicolich) dell'Ospedale Regina Elena di Trieste. Paper. Price 45 lire. Pp. 282 with 76 illustrations. Bologna: L. Cappelli, 1931.

The work is divided into two parts, the first considering the subject in general and the second presenting numerous illustrations of intravenous pyelography in almost all disturbances of the kidney, including such rare lesions as echinococcus cyst. The initial portion of the monograph outlines the principles, technique and limitations of ascending pyelography based on 200 selected cases. It then describes the history of the development of descending pyelography, the early use of iodized urea and the peroral method of Ziegler and Kohler. Iopax is minutely described as to its history, chemical and physical properties, toxicity, antiseptic action, technique of administration, indications and contraindications and tolerance. A chapter describes the

methods of using intravenous pyelography by Iopax for the evaluation of renal function. Finally ascending and descending pyelography are compared, the advantages and indications for the two methods being thoroughly considered. Ravasini is enthusiastic over the results obtained by the intravenous method.

UNTERSUCHUNG DER URINARIE HARSTEINE. Von S. Okawa. Monographiae Actarum Dermatologicarum C. Series Urologica No. 2. Paper. Pp. 52. Kyo-o Institut Dermatologisch Universitatis Imperialis, 1929.

The author examined 177 urinary calculi which were obtained from 94 patients. The stones were examined chemically with especial reference to the quantitative values of the various urinary salts. Many stones were analyzed after division into central middle and outer layers, others were cut into sections from 0.2 to 0.02 mm in thickness and studied microscopically. Various types present different important characteristics, particularly in regard to their surface, the size of the component crystals and other interesting features of chemical interest.

THE ELECTROCARDIOGRAM. By W. H. Crumb. Medical Research Council Special Report Series No. 147. Paper. Price 1s. 3d. Pp. 57 with 11 illustrations. London: His Majesty's Stationery Office, 1930.

This monograph is a valuable contribution especially helpful to those who wish to understand the principles underlying the production and interpretation of the electrocardiogram. It may not interest the average practitioner as it is highly technical, dealing with many questions of physics especially with electricity as they concern the physiology of the heart. It is a most creditable piece of investigation and is admirably presented.

CRITICAL STUDIES IN THE LEGAL CHEMISTRY OF FOODS FOR CHEMISTS, FOOD INSPECTION OFFICIALS AND MANUFACTURERS AND DEALERS IN FOOD PRODUCTS. By K. O. Brooks, B.Sc. Consulting Food Inspector. Chemist. Cloth. Price \$6. 1p. 280. New York: Chemical Catalog Company, Inc., 1927.

This is largely a compilation of information on the legal aspects of the chemistry of some of the important classes of foods. The articles have been previously published by the author in various technical and trade journals. The book is written in simple language understandable to the intelligent layman. The significance of compiled chemical facts and data for foods with respect to food laws, regulations and standards is considered. Analytic data little known to the average chemist and layman are drawn from various chemical journals, federal state and Canadian food inspection reports, and reports of the U. S. Bureau of Chemistry and the Connecticut State Experiment Station. Chapters are devoted to the legal chemistry of fruits and fruit products, vinegars, interpretation of a vinegar analysis, legal chemistry of some condimental sauces, edible oils, cacao products, spices and maple products. The appendix furnishes some miscellaneous information on standards and definitions for fruit and fruit products, how carbonated fruit beverages are made, investigation of methods of preparing carbonated beverages from fruits, requirements of pectin for the commercial jelly makers, the importance of sugar in determining texture, flavor and yield of jelly, research on the manufacture of mayonnaise, report on a cooperative research on mayonnaise and the labeling of beverages and beverage materials under the federal Food and Drugs Act. The book is especially serviceable as an aid to the detection of adulteration of the foods discussed, for the interpretation of analyses in problems dealing with food laws, and for correlation of chemical composition, food inspection decisions and food standards. Much valuable information and data are made readily available in the discussions and tables. The meaning of the various chemical determinations used in food analysis is well considered. The book should serve as an excellent guide and aid in the ordinary problems involving commercial foods, their chemical composition and their legal status under the food laws.

DIE FILTRIERTAREN KRANKHEITSERREGER UND NEUES ZUM TUBERKULOSEPROBLEM. GEDAENKEN ZUR VERERBUNGSWISSENSCHAFT AUF GRUND VON STUDIEN AN DER LAHMKRANKHEIT (RHEUMATISMUS) DER HAUSTIERE IN IERT. Von Dr. Med. Vet. Fritz Mrowka. Veterinär Institut der Hacienda Casa Grande in Peru. Paper. Price 15 maris. Pp. 208 with 114 illustrations. Leipzig: Johann Ambrosius Barth, 1931.

This is an interesting but highly speculative thesis tracing certain diseases including several produced by filtrable viruses to lipoprotein intoxication and autonomous development of the specific causative micro organisms from fat droplets.

Medicolegal

Liability of Third Person for Medical Fees

(*Swarens v Pfinsel (Mo) 26 S W (2d) 951*)

Pfinsel was burned in a gasoline explosion in the course of his employment. His cousin, Mrs. Amel, with whom he boarded, requested Dr. Swarens to render medical services and promised to pay his bill. Pfinsel was unconscious when Swarens first visited him and at no time said anything to Swarens about employing him. Swarens, however, did not charge Mrs. Amel on his books for his services; he made the charge to Pfinsel. He rendered no bill to Mrs. Amel, but when his services ended, he, at Mrs. Amel's request, delivered his bill, made out against Pfinsel, to Pfinsel's attorney, who was negotiating for a settlement with the insurance company by which Pfinsel's employer was insured. Swarens' bill was not paid, so he sued Pfinsel and Mrs. Amel jointly. Judgment was rendered against both of them, but Mrs. Amel appealed, ultimately carrying the case to the Supreme Court of Missouri, Division No. 2.

Mrs. Amel contended that her promise to pay Swarens for his services was void, because it was not in writing, since the statute of frauds provides that "no action shall be brought to charge any person upon any special promise to answer for the debt, default or miscarriage of another person" unless the agreement is in writing. Her contention said the Supreme Court, was well taken, citing *Price v Chicago, M & St P Rd Co*, 40 Mo App 189, to show that if the beneficiary under a promise is liable at all, the promisor not being solely liable, the promise comes within the statute. Ordinarily, said the court, the question as to whom credit was given is one for the jury. The fact that Swarens' charges on his books were against Pfinsel alone, and not against Mrs. Amel, might not be controlling as a matter of law. The fact, however, that he sued both Pfinsel and Mrs. Amel, alleging that he had rendered services at the instance and request of both of them and prayed judgment against both shows beyond any question that credit was given to some extent at least to Pfinsel. In view of his conduct Swarens cannot say that credit was extended Mrs. Amel alone. The fact that Swarens presented a bill made out to Pfinsel to Pfinsel's attorney tended further to prove that credit was extended in part at least to Pfinsel. The court held, therefore, that the promise made by Mrs. Amel came within the statute of frauds and was void because it was not in writing. The judgment of the court below, against Mrs. Amel was reversed.

Compensation for Traumatic Neuroses

(*Welchlin v Fairmont Railway Motors (Minn) 250 N W 897*)

Welchlin was hit on the inner side of his right leg, near the groin by the handle on the carriage of a lathe at which he was working. A persistent limp followed. Welchlin instituted proceedings to obtain compensation under the workmen's compensation act. At the time of the final hearing before the industrial commission, about five months after the accident, he had a straddling movement of the leg, which gave him a straddling gait. He was doing bookkeeping apparently trying to learn, and getting nothing for it, although there was other work he might do.

Three physicians called by Welchlin testified that he was unable to work at his former employment, although his disability was not total. Two physicians called by the employer testified that he had suffered no serious injury, that he had recovered, that he could return to work if he would, and that his limp could be accounted for on the theory of a traumatic neurosis and was not disabling. There was no claim that Welchlin was actually or consciously malingering. One of the physicians who testified for the employer was of the opinion that a settlement of the case would not cause a disappearance of the limping but that if the case was settled and Welchlin got back to work at his machine he would forget his limp and a normal gait would be reestablished. The other medical witness called by the employer was of the opinion that the limp

was due either to habit or to a traumatic neurosis. The commission awarded Welchlin compensation for temporary total disability up to the time of the hearing. It found, however, that at that time there was no disability whatever. Welchlin thereupon appealed to the Supreme Court of Minnesota.

Under the Minnesota workmen's compensation act, said the Supreme Court, the injured workman does not recover damages for an injury; he receives a stated compensation, fixed by the statute as compensation for disability. He may have compensation for a neurosis if it is the proximate result of his injury and causes disability. A helpful statement of the situation in such cases as this appears in *Lares v Blainchdah Colliery Co* (1909) 2 K B 73 where the English court, in reversing the decision of a lower tribunal denying compensation, said:

The learned judge says he thinks that although the man honestly believes he is not able to do the work and although he is not shamming or malingering it is sufficient for the employers to show that the muscular mischief is at an end. I am entirely unable to assent to that view. The effects of an accident are at least twofold: they may be merely muscular effects—they almost always must include muscular effects—and there may also be and very frequently are effects which you may call mental or nervous or hysterical whichever is the proper word to use in respect of them. The effects of this second class as a rule arise directly from the accident from which the man suffered just as much as the muscular effects do, and it seems to me entirely a fallacy to say that a man's right to compensation ceases when the muscular mischief is ended though the nervous or hysterical effects still remain.

The evidence in the present case, said the Supreme Court, does not indicate that the partial disability will last long. It may take some effort on the part of the workman to put him self into normal condition and there may be attendant pain. But said the Supreme Court we are unable to see how it can be found that no disability remains. There is a limited partial disability; the finding of the commission is not sustained. The order of the industrial commission was therefore reversed.

Evidence from Unauthorized Autopsy

(*Streipe v Hubbuch Bros & Ellendorf (Ky) 25 S W (2d) 558*)

Streipe in the course of his employment fell from a ladder some eighteen or twenty feet high and died in a few minutes. He had always enjoyed the best of health and appeared in good health when he left home on the day of his death. Without the consent of his widow, an autopsy was performed. His widow applied to the workmen's compensation board for compensation. The physician who performed the autopsy and two physicians who attended at the instance of the insurance carrier testified that Streipe was suffering from myocarditis which in their opinion caused his death, and the workmen's compensation board refused to give compensation. The order of the board was affirmed by the circuit court, and an appeal was taken to the Court of Appeals of Kentucky.

The only point at issue was the admissibility of the evidence of the physicians, based on the unauthorized autopsy. Without that evidence the finding of the workmen's compensation board was without support. On behalf of the widow it was contended that the evidence was not admissible because the inquest was illegally held. But even if the illegality of the inquest be conceded, said the Court of Appeals, that fact would not render the evidence of the physicians inadmissible. As a general rule applied in practically all jurisdictions, courts do not concern themselves with the method by which a party has secured the evidence which he adduces. Evidence which is otherwise admissible will not be excluded because it was fraudulently, wrongfully or illegally obtained, with the single exception that evidence obtained by search or seizure contrary to constitutional inhibitions is inadmissible in criminal cases. In the present instance the proceeding was civil, not criminal. Moreover the language of the constitution is: "The people shall be secure in their persons, houses, papers and possessions from unreasonable search and seizure." The words "persons," "houses," and "papers" may be excluded from consideration as not descriptive of a corpse. The only question is whether a corpse is a "possession." The word "possessions" includes nothing but property and is confined in its application to things intimately associated with the person. The widow has certain rights in the corpse of her deceased husband but the authorities uniformly hold that there is no right of property in the ordinary sense of that term in the dead body of a human being. A corpse, said the court, is

not a possession and an autopsy is not an unreasonable search and seizure within the contemplation of the constitution.

Even though the coroner's report of the inquest was inadmissible and was properly excluded, the workmen's compensation board did not err in admitting the evidence of the physicians as to what they saw during the autopsy. It was proper for them to give their opinions as to the cause of death.

Death from Inhalation of Poisonous Fumes

(*Adler v Interstate Porter Co (Minn.) 250 N W 486*)

Adler a stoker, in the course of his employment pulled out a charge from an upper retort and was exposed to the fumes of coal and coke. When he completed the task he complained of a pain in his head and across his chest. He felt sick and vomited severely. He ceased work and was taken home and placed in a chair from which he fell a few moments later and died. Immediately thereafter an autopsy was performed. In compensation proceedings instituted by the widow the pathologist who performed the autopsy testified before the industrial commission that Adler's body was that of one of the healthiest men he had ever examined and that in his opinion Adler died "as a result of probably inhalation or injection of some poisonous substances presumably derived in some way or other from the destructive distillation of coal. The conclusion of the pathologist was not disputed nor was any other cause of death suggested. The commission nevertheless denied compensation. The widow appealed to the Supreme Court of Minnesota which reversed the decision of the commission.

All causes of death other than the inhalation or injection of poisonous substances coming from the distillation of coal and the Supreme Court, were eliminated, so far as was possible in the hearing before the industrial commission. The conclusion of the pathologist was not disputed. No cause other than the one he assigned was suggested. It compensation be denied the opinion reached by a competent pathologist given with a rather definite degree of certainty after a thorough an autopsy as could be performed and under as favorable conditions as could be had, must go for weight, and the cause of death be unascertained. This cannot be so. It is true that the physician could not testify as to an exact certainty. He could not give the definite gas or poisons or combination which brought about the result. It is true that he admitted under cross examination that in reaching results there might be such a thing as conjecture or speculation. There is no question of his credibility. The burden of proof of course, is on the claimant and she cannot rest a recovery merely on speculation or conjecture. In the practical administration of the compensation act however the unassured opinion of the physician, with the uncontradicted circumstances supporting it, should be taken as a correct statement of cause of death.

The employer and the insurance company, however contended that even conceding that death came from an inhalation or injection of gas or poison it was not an accident. The workmen's compensation act said the Supreme Court defines an accident as 'an unexpected or unforeseen event happening suddenly and violently with or without human fault and producing at the time injury to the physical structure of the body.' G S 1923 (1 Mason 1927) Sec 4326(h). The evidence here presented clearly indicates an accidental injury.

Malpractice Care and Skill Correlated—The physician owed the plaintiff a duty to exercise ordinary care and skill. His failure to exercise either would be negligence. If he was incompetent and attempted an operation which he knew he could not perform it would be negligence. So the term negligence covers not only a lack of care but also failure to exercise skill which the person possesses and the attempt to exercise skill which he knows he does not possess.—*Rothschild v Baerl (Mo.) 26 S W (2d) 760*

Malpractice Unpleasant Taste Not Actionable—An unpleasant sensation as a result of the negligent act of another without physical or material damage, cannot be the basis of an action for damages. Where through the negligence of a dentist a patient is caused to swallow a bitter and ill tasting liquid, but sustains no ill effects other than the disagreeable stimula-

tion of the sense of taste, the patient has suffered no actionable damage. The mere fact that one event chronologically follows another is insufficient to prove a causal relation between them. Evidence that a woman suffered a pain in her heart and other physical ailments after having swallowed a liquid—the nature and character of which does not appear, except that it was suitable for hypodermic use by a dentist, while operating in a patient's mouth and possessed a bitter and disagreeable taste—is, in the absence of evidence tending to show a causal relation, insufficient to authorize an inference of fact that her condition was caused by swallowing the liquid.—*Payne v Chandler (Ga.), 153 S E 66*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal Diseases of Children, Chicago

- Whooping Cough in Children Stridorous and Asthmatic Breathing C. Jackson Philadelphia—p. 153

Sonne Dysentery—Attention is drawn by Nelson to the possible importance of *Bacterium dysenteriae* Sonne as a cause of dysentery in children. Methods for the isolation and identification of the organism are given. Clinical features of the disease with eight case histories and clinical charts illustrative of the mild and severe forms are given.

Tuberculosis in Schools in Colorado—A survey for tuberculosis made by Forbes et al. in the school of a small community composed largely of health seekers where contact with the disease is unusually great, showed 36.4 per cent of 283 children from 4 to 15 years of age to be infected. This is only a moderate increase over the incidence noted in nontuberculous communities. Roentgen studies of the 103 children giving positive reactions revealed childhood tuberculosis in 19, or 67 per cent, of the whole group the average for the country at large varying from 1 to 4 per cent. No child with the adult or exudative type of tuberculosis was found. Most of the children reacting positively and those having actual childhood tuberculosis were not born in Colorado. Climatic factors in Colorado apparently exert a favorable influence in the protection of children against active tuberculous infection. In this study the father was the source of infection in 64.8 per cent of the children giving positive reactions and the mother in only 12.6 per cent. Symptoms of fatigue, undernutrition and a history of frequent colds are said to be not reliable aids in the diagnosis of childhood tuberculosis.

Loewenstein's Ointment for Immunization Against Diphtheria—Twenty-six, or 55.3 per cent of forty-seven children who were given three injections of Loewenstein's ointment for active immunization against diphtheria gave negative reactions to the Schick test within six weeks. No local or general reactions were noted by Kegel and Gasul.

Rickets Colorado Sunshine in Prevention—Experiments made by Stein and Lewis show that in Colorado direct sunlight in June and July has a marked antirachitic action on rats, even when the average daily exposure is as little as three and three fourths minutes. Only a mild degree of rickets is evident in rats exposed to direct sunlight for seven and one-half minutes. The high antirachitic potency of Colorado sunshine may be explained by the fact that the atmosphere is relatively free from moisture and smoke. Sunshine has an apparent beneficial effect on growth.

Antirachitic Effects of Winter and Summer Sunshine in Colorado—The experimental results obtained by Lewis et al. do not support the contention of Tisdall and Brown at least as far as Colorado is concerned, that suddenly about the first of March there is a marked increase in the amount of ultraviolet radiations reaching the earth. There is no marked difference in the antirachitic effect of winter and summer sunshine in Colorado. The comparatively high antirachitic action of Colorado sunshine with relatively little seasonal variation as compared with that of other places where similar studies have been made may be explained on the ground that throughout the year relatively short wave radiations reach the earth as a result of the high percentage of winter sunshine, the low humidity and the small amount of smoke in the atmosphere.

Ulcerative Laryngitis—A case of fatal ulcerative laryngitis due to an atypical organism resembling the diphtheria bacillus and producing only a slight fibrinous reaction is reported by Bullova and Jacoby. The organism yielded by a culture from a laryngeal ulcer was identified as the *Corynebacterium ulcerans* of Gilbert and Stewart previously isolated only from nonfatal upper respiratory infections. Both organisms produce extensive necrosis and ulceration without the formation of a typical diphtheritic pseudomembrane. The immunologic study of cases of diphtheria not responding to antitoxin is suggested.

Juvenile Embolic Gangrene of Upper Extremity—A case of aortic stenosis of rheumatic origin with an accompanying embolic gangrene of the right hand in a child is reported by Craig and Muns.

- *Infectious Cirrhosis H. E. MacMahon Boston—p. 77

Inclusion Bodies of Fowlpox and Molluscum Contagiosum—Goodpasture and Woodruff state that the inclusion bodies of molluscum contagiosum may be freed from surrounding cellular material by tryptic digestion. Unlike fowlpox

inclusions, the molluscum bodies are found to be sticky and gelatinous after they have been digested. Because of this characteristic they cannot be manipulated readily with the Chambers microdissection apparatus. The gelatinous matrix of the molluscum bodies has a markedly granular appearance, owing to the presence within it of myriads of Lipschutz granules—minute coccoid structures, 0.25 micron in diameter. These granules are identical in size, shape and staining reactions with the Borrel bodies of fowlpox. They are resistant to the action of trypsin. The inclusion bodies of molluscum, on being placed in distilled water show little or no swelling. Under similar conditions the fowlpox inclusions swell markedly, as the result, probably of their lipid material acting as a semipermeable membrane. Trituration of the molluscum inclusions readily breaks them up into the component Lipschutz granules. Fowlpox inclusions similarly treated fail to break up so readily into Borrel bodies. This difference in the reaction of molluscum and fowlpox to trituration may afford an explanation for the relatively greater filtrability of the former. Fowlpox and molluscum contagiosum are apparently specific for fowls and man, respectively. Cross inoculation experiments having proved unsuccessful. Attempts to transfer molluscum to monkeys and other laboratory animals were also unsuccessful.

Transformation of Sinusoidal Endothelium into Capillary Type.—In granulation tissue produced within the liver of rats, McJunkin noted that the capillaries may arise in the usual way by angioblastic proliferation or sinusoids may persist as capillaries. In both instances the vessels are continuous with the sinusoids in the adjoining lobules. With loss of contact with living hepatic epithelium the endothelium becomes less phagocytic. The peculiarities of sinusoidal endothelium depend on its functional activity, which in turn is determined by its normal histologic position. From the behavior of sinusoidal endothelium present in granulation tissue, it appears not to be a distinctive type of cell.

Polymorphocellular Tumors in Region of Knee.—Hunter describes two instances of benign polymorphocellular tumors occurring in the region of the knee in closely related persons. In the daughter, the new growth originated in the synovial membrane, a rare site for the formation of tumors and was benign. In the father, the tumor was of exceptionally long duration, attained very bulky dimensions and although exhibiting locally destructive properties also appears to have been benign. Because of the large size and extensive ramifications of the mass, the point of origin could not be determined, but certain facts point to an extra-articular source. Most commonly, new growths of the type reported arise from the sheaths of tendons and only rarely from the capsule or synovial membrane of joints. In the latter event the knee is much more frequently involved than any other joint in the body. The rarity of such growths of the joints is evidenced by the fact that the author was able to collect from the literature, in addition to his own cases, only forty-four instances of closely similar or identical tumors.

Circulatory Pattern in Islands of Langerhans.—Beck and Berg made anatomic studies of the circulatory pattern in the islands of Langerhans in white mice. The arrangement consists of a network of capillaries which are supplied with blood through afferent arterioles, empty into efferent venules, and anastomose freely with intercapillary capillaries. An analysis of the vascular system of the islands shows that the arrangement of the vessels favors the circulation of a large volume of blood with maximum efficiency. Since the arterial pressure diminishes directly with the length of the vessel it is higher at the end of a short arteriole than at the end of a longer one assuming the diameters to be equal. Therefore the short direct arterioles to the islands afford a higher pressure for the column of blood entering the capillary network than the long arterioles supplying the capillaries of the acinar tissue situated at the periphery of the lobules. When the capillary bed of the islands is larger, more than one arteriole is present. On the venous side the multiple short efferent venules of the islands insure a low venous pressure with minimal resistance to the egress of blood. Regardless of the position of the islands in the pancreatic lobules the dynamics of the circulation remain unaltered. These pressure relationships explain why the islands remain intact in

advanced chronic passive congestion, whereas the acini in the peripheral parts of the lobules undergo extensive atrophy. On the one hand, the pressure in the short arterioles to the islands is sufficient to overcome the increased resistance in the venous system. On the other hand, the pressure in the arterioles to the outlying acini is insufficient to overcome the venous resistance, which is augmented by stasis in the long efferent venules. As a result, the nutrition of the islet cells remains undisturbed while degeneration of the acini occurs. The few acini that remain intact are found in the immediate vicinity of the islands, where the circulation is best. When thrombosis, embolism, sclerosis or spasm of the afferent arterioles occur, the capillary anastomoses can form a collateral circulation, which maintains an adequate blood supply to the islands. This mechanism probably accounts for the few changes that are observed in the islands in the presence of arteriolar lesions. Examination of the circulatory patterns of the islands of Langerhans in the pancreas of the guinea pig, white rat, monkey and man revealed that they were similar to those of the white mouse.

Interacinar Epithelium of Thyroid.—Moritz states that in normal thyroids of fetuses, children and adults, in pathologic glands the seat of hypertrophy and hyperplasia, in nodular goiter, and in adenomas of the thyroid, the mechanics of hyperplasia are essentially similar. New follicles are formed by intrafollicular and extrafollicular proliferation of epithelium and the secondary follicles may lose their parent connection and become isolated units. In the scattered foci of hyperplasia in normal thyroids, as well as in glands that are the seat of pathologic hypertrophy and hyperplasia, labyrinthine intercommunication of acini exists and is probably limited to the connection of primary with secondary acini. Solid masses of undifferentiated interfollicular epithelium are found in both normal and pathologic glands, but such masses are readily accounted for as detached extrafollicular buds. Evidence contrary to certain observations by Rienhoff concerning the mechanics of hyperplasia in the thyroid is presented.

Experimental Glomerulonephritis in Monkey.—Bell and Clawson produced a form of chronic diffuse glomerulonephritis in a monkey by repeated intravenous injections of streptococci over a period of four years. The lesion was characterized histologically by marked increase in capillary endothelium and increase in the thickness and number of layers of the capsular basement membrane. Histologically the glomerular lesion resembled human lipoid nephrosis of mixed type, except that no fat was present.

Hypernephroma with Tumor Thrombosis of Vena Cava and Heart.—Polyses and Trift report a case of hypernephroma with malignant thrombosis by invasion of the inferior vena cava and heart. It is the fifth case described and was unique in its extent of involvement. The entire inferior vena cava and all its main tributaries (ilic, renal and hepatic veins) were occluded by a continuous malignant thrombus which extended into the right atrium, through the tricuspid valve into the right ventricle. The cardiac involvement here was even more extensive than in the case described by Weber, in which the thrombus did not extend beyond the right atrium. Another interesting feature was the fact that, in spite of the massive involvement of the inferior vena cava and the right kidney, the right suprarenal remained singularly free from metastasis.

Chronic Typhoid Cholecystitis.—Mallory and Lawson describe the gross and histologic appearance of the gallbladders of seven typhoid carriers. A common histologic picture was found. A review of 400 routine slides of chronic cholecystitis showed a similar lesion in 65 per cent of the cases. A review of the clinical histories showed that only 49 per cent of the cases with negative histories showed this picture, as against 25 per cent of cases with positive histories. It is felt that the lesion described is characteristic of chronic typhoidal cholecystitis but not pathognomonic of it. It is suggested that it is not specific of any organism but represents a reaction to persistent infection of the bile in contrast to the more usual type of chronic cholecystitis with sterile bile and persistent infection of the wall.

Infectious Cirrhosis.—According to MacMahon uncomplicated infectious cirrhosis is one of the rarer diseases of the liver. It is caused probably in most instances by the colon

bacilli and is characterized by a variable degree of connective tissue and bile duct proliferation about the portal trunks. Obstructive cirrhosis resulting from prolonged biliary obstruction is a much more common condition although less conspicuous and hence frequently overlooked. Most cases of infectious cirrhosis are found in combination with obstructive cirrhosis but even this combined type is relatively rare and is almost invariably fatal.

Peptic Ulcer Diagnostic Value of Roentgen Ray —

A study has been made by Emery and Monroe of the value of the roentgen ray to the clinician in following the treatment of patients with ulcer of the stomach or duodenum. The accuracy of the roentgen examination is shown to be high as compared with most kinds of laboratory procedures. However, it is a mistake for clinicians to place implicit confidence in the results of the roentgen observations and to discard entirely the older methods of investigation. It was found that a correct diagnosis was reached in 93 per cent of those patients having an ulcer. Retention as shown by roentgen examination was found to give a true picture of clinical retention in 67 per cent of cases. The presence or absence of tenderness over an ulcer was found to have no clinical value. A study of the roentgen observations and the clinical symptoms shows that it is not possible to diagnose a healed duodenal ulcer by the roentgen ray. Moreover the data support the idea that duodenal ulcer is a chronic disease which is rarely cured by treatment.

Traumatic Myelitis Due to Fracture of Spine —Gurdjian asserts that roentgen studies are important in cases of fractured spine with cord injury. Although films can be of aid in diagnosis, they should always be considered in association with other methods of clinical and laboratory approach. Some cases of certain transection of the cord on the basis of roentgen observations may not show any signs of cord damage even on neurologic examination.

Recoil Following Visceral Decompression —Wheeler emphasizes the fact that when an organ or system is suffering directly from pressure effects or indirectly from back pressure the greater the pressure the more gradual should be its relief.

This applies particularly to such conditions as uremia following the release of back pressure on the kidneys, hepatic shock in portal obstructions or obstructions of the common duct with or without ascites, toxemia and other morbid conditions in the presence of intestinal obstruction and flapping mediastinum in acute emphysema. The dangers attending a too generous tapping of the pleural or peritoneal cavities for effusions and the risks of spinal puncture when the pressure is high, are also included. The problems involved however are by no means confined to the realm of surgery. One finds patients with back pressure on the heart from disease and narrowing of the arteries with resultant hypertrophy, dilatation and cardiac failure. As the back pressure continues and increases compensation fails and secondary lethal changes (often renal) complete the picture. If it were possible by the use of drugs to reduce the blood pressure suddenly the cure would be admittedly worse than the disease. Cardiac and renal failure would inevitably result. Physicians must take only those depressor drugs should be chosen which have the slowest and most prolonged action. Anesthetists are alive to the dangers of sudden decompression. Anesthesia by spinal injection or chloroform inhalation must be cautiously adopted or entirely avoided in the presence of high blood pressure. The rapid fall so frequently noted in either of these methods is employed produces at times an alarming reaction including sudden failure of the cardiac pump or stoppage of renal function. In ophthalmic departments the ophthalmologist deals with glaucoma by the very slow withdrawal of aqueous humor from the anterior chamber. By gradual decompression vascular dilatation, intraocular hemorrhage and retinal detachments are avoided. Obstetricians are concerned in cases of hydramnios. If the formation of fluid is slow the system accommodates itself to the increasing pressure but if it is rapid the circulation suffers, the lips, hands and feet become cyanosed, there is indigestion and vomiting and albumin appears in the urine. Bursting of the membranes, on the other hand, causes a recoil that induces syncope by rapid reduction of intra-abdominal tension. When inducing labor in cases of hydramnios the obstetrician lays especial stress on the necessity for preventing a sudden outpouring of the fluid. To effect this control and to insure the slow escape of the waters a very small or valvular aperture is provided. Again in cases of imperforate hymen leading to hematocolpos the obstructing membrane is punctured with a trocar and cannula and the fluid allowed to drain slowly away during the first twenty-four hours. If the fluid is not drained slowly the patient may pass into a condition that is usually described as one of extreme shock.

Analgesia and Anesthesia in Childbirth —McIlroy states that each maternity case must be given individual attention with regard to the most suitable sedative and anesthetic to be employed. The age, parity, temperament, general health and complications if present must all be carefully considered. Obstetric anesthesia is not quite comparable with the surgical form. The pain is prolonged and has to be combated with sedatives as well as with anesthetics. The effect of these sedatives must be taken into consideration when an anesthetic is decided on. Light anesthesia is of little use in surgery while it is generally employed in midwifery practice except in cases in which operative intervention is required. The action of the uterus must be maintained and hemorrhage after delivery must be prevented as far as possible. The expenditure of time with its consequent financial complications is a consideration. It is desirable that private patients should have the continuous attendance of the practitioner during labor, if sedatives or anesthetics are to be given just as in a hospital practice. It is a common mistake to carry out violent methods of artificial respiration in the infant does not breathe immediately after birth. One has to remember that it is narcotized to some extent and requires time to recover warmth and clearance of its respiratory passages are sufficient in most cases of delayed respiration but carbon dioxide and oxygen should be given if there is any undue delay.

Paranasal Suppuration Persisting After Operation —Goldsmith believes that persistence of discharge from the maxillary sinus after operation does not necessarily require further surgical measures of a more radical nature. The main symptoms for which the patient consulted the physician are

as pain or discomfort in the head, nasal or postnasal discharge, nasal obstruction, recurring "head colds" or mental depression or lessening of the power of concentration, may have been so greatly benefited that even if some nasal or sinus secretion persists it may not be of sufficient importance to require further instrumental intervention. The extraordinary efforts made to detect the slightest amount of mucoid secretion in an accessory air cell and the ridiculous importance allotted to its presence are further evidences of the extent to which the subject of foci of infection has clouded clinical vision and made physicians forget their elementary physiology. Taking each cavity by itself the author enumerates some of the reasons for failure in operative treatment to secure complete relief from undue secretion.

Administration of Gastric Antacids—An examination of the literature on this subject by Johnston and Henderson revealed the fact that sodium bicarbonate is now much less favored than it was some years ago. If excess amounts of sodium bicarbonate or of magnesium oxide are added to a hydrochloric acid solution of the strength of gastric juice (0.3 per cent) the solution becomes alkaline within one minute, but the alkalinity produced by sodium bicarbonate and magnesium oxide leads in turn to a fresh secretion of gastric juice. If sodium citrate is added to such a solution of hydrochloric acid, the mixture will give an acid reaction with certain indicators and a neutral reaction with others. One would expect to find in such a mixture sodium chloride, some sodium citrate, citric acid and a trace of hydrochloric acid. Apparently it would contain as much acid as the original hydrochloric acid and by titrating the mixture with sodium hydroxide solution and a suitable indicator this would be the result obtained. But today, acidity is judged rather by the amount of free hydrogen ion present, and by this standard the mixture will have a neutral reaction which is expressed as pH 7.0. The original hydrochloric acid solution would be very acid (pH 1.0). This is due to the fact that the citric acid in such a solution largely exists as citric acid and liberates very few hydrogen ions while in such a hydrochloric acid solution almost all the hydrogen ions are free. The same type of reaction occurs with potassium citrate or any acetate. If tribasic calcium and magnesium phosphates are added to an artificial gastric juice the mixture becomes neutral (pH 7.0) in a minute and stays neutral. Calcium carbonate brings about neutrality more slowly, but the mixture does not become alkaline (i. e., does not attain a pH of more than 7.0). Bismuth carbonate only reduces the acidity (to pH 4.0). By weight, magnesium oxide is the most efficient neutralizer. About four times as much sodium bicarbonate and five times as much of the citrates or tribasic phosphates are required.

Pituitary Posterior Hormone in Fat Metabolism—On the basis of a series of experiments on dogs, Raab states that large subcutaneous or smaller intraventricular doses of pituitary extract decrease the neutral fat content of the blood. The reaction is abolished by mechanical destruction or pharmacologic paralysis of the centers in the tuber cinereum, after transection of the spinal cord, after paralysis or section of the abdominal splanchnic or after paralysis of the latter with ergotamine, or after phosphorus poisoning. An accumulation of fat in the liver and a decrease of the peripheral tissue fat has been noted after injection of pituitary extract. The conclusion is drawn that pituitary extract promotes the absorption and destruction of circulating fat by the liver through a nervous pathway starting in the tuber cinereum and running through the cervical spinal cord and the abdominal splanchnic to the liver. Any disturbance of the cooperative pituitary-mesencephalic system would lead to a retention of excess amounts of fat in the body and

thus lead to obesity. Comparative determinations of arteriovenous fat suggest that pituitary extract does not affect deposit fat directly. There seems to be a close relationship between the pituitary extract-nervous mechanism for fat destruction and the so-called chemical heat regulation. The author has observed verified cases of purely hypophyseal and purely mesencephalic obesity.

Iodine Reaction in Exophthalmic Goiter—According to the Thompsons in Boston the smallest amount of iodine that will produce any reduction in basal metabolism in exophthalmic goiter is greater than 0.75 mg. daily in about two thirds of the cases. The minimum amount that will produce a maximum reduction is roughly 6 mg. daily in the majority of cases. Between these two limits, the relation between the percentage approach of the basal metabolism toward the normal level and the size of the dose is roughly linear. The effective dose has not been determined in Chicago but it is known that 6 mg. a day will cause a marked reduction in basal metabolism in some cases. Iodine must be administered at a certain minimum rate in order for the maximum effects to be produced. It also appears that this rate may be one that is sufficient to cause colloid to be stored at an adequate rate. In a few cases the reaction to iodine is reversible. The administration of a small dose such as 15 mg. daily may sometimes interfere with the effect of a much larger dose administered immediately afterward. In the routine treatment of the disease, it is desirable to give initially an excess of iodine sufficient to produce maximum effects. The amount necessary to do this is undetermined but probably is not more than 30 mg. (roughly 5 drops of the compound solution) daily. In patients who develop refractoriness to iodine it is wise to postpone operation until iodine has been omitted long enough to allow the refractoriness to disappear. In a large percentage of mild cases of the disease improvement may be maintained for long periods by iodine, whereas moderately severe or severe cases rarely show more than temporary improvement. Myxedema may occasionally develop during the administration of iodine to patients who have a normal basal metabolism following subtotal thyroidectomy for exophthalmic goiter and to patients with mild untreated cases of the disease.

Effect of Anterior Pituitary Extract on Albino Mouse—Johnson and Hill found that the daily injection of bovine anterior pituitary extract (alkaline, later neutralized and filtered) into twenty-one female and fourteen male albino mice produced an increase in growth over that of eleven control females and fourteen control males, which were injected with physiologic solution of sodium chloride. This increase was more marked in the females than in the males. The extract produced a marked increase in the size of the ovaries after the age of 55 days through excessive lutein body formation and persistence. Only one experimental female had a normal ovary with the few corpora lutea associated with normal function, and this was a pregnant animal. Increased lutein formation was associated with a high degree of sterility, but apparently also with an excess number of tubal ova. None of the control females had an excessive number of corpora lutea. In the injected male mice, seven showed a hardening of the testicular wall. Some showed an increase in interstitial tissue and there was some destruction of seminiferous epithelium. Excess colloid was formed in some of the Cowper's glands. The experimental male mice showed a high degree of sterility compared to the normal males.

Allergic Headache—Until more knowledge is obtained regarding migraine and further clinical studies are made of the type of headache induced by the ingestion of specific food, it is suggested by Eyer mann that the term "allergic headache,"

rather than "allergic migraine" he employed to describe this condition. It is suggested that either increased intracranial pressure or cerebral edema may be the pathologic causation and that in some instances the condition may be analogous to, or a manifestation of, angioneurotic edema.

Skin Tests to Foods in Asthma—Skin tests to foods made by Rackemann in a series of 595 patients gave positive results in 32.3 per cent of the 207 children and 21.8 per cent of the total. Foods which reacted most commonly were wheat and eggs. Positive tests to foods may or may not be of clinical importance, as shown by illustrative cases. Despite a negative skin test, specific food sensitiveness may exist.

Allergic Dermatitis—Success in the treatment of allergic dermatitis, Stroud says, is proportionate to knowledge of the causative factors. In a series of fifty cases positive skin reactions occurred in twenty-four. With institution of antiallergic measures eight patients were relieved and thirty-two were improved.

Paroxysmal Hemoglobinuria—A case of paroxysmal hemoglobinuria is reported by Swineford. He wonders whether an appreciable number of anemias of late syphilis may not be due to unrecognized abortive, subhemoglobinuric attacks of paroxysmal hemoglobinuria.

Fatal Anaphylaxis in Man—A case of sudden death following the injection of foreign protein is reported by Sheppe with complete postmortem observations. It is offered as an example of true fatal anaphylaxis of the bronchospastic type in man. Fifteen other cases coming to necropsy are analyzed. Evidence is offered to show that thirteen of these cases were probably examples of true anaphylaxis in man. In each of the thirteen instances death occurred either from bronchospasm or splanchnic dilatation. The theory is advanced that an entirely different mechanism (possibly thymicolymphatic) is responsible for post-injection deaths not exhibiting bronchospasm or splanchnic dilatation at necropsy. It is urged that all fatalities from injection of serum be subjected to necropsy for (a) elimination of other and unsuspected causes of death, (b) recording of careful observations relative to the condition of the pulmonary, thymicolymphatic and splanchnic systems, and (c) accurate classification of type of reaction based on anatomic observations.

Schilling Index in Appendicitis—The Schilling index, white count and microscopic observations were noted by Goodale and Manning in forty appendectomies, ten appendices

were acutely inflamed. There was a definite shift to the left or an increase in young forms of the neutrophils in the acutely inflamed appendixes. The remaining appendixes showing no acute pathologic changes had little or no increase in young forms despite an increase in several of the white counts. The white counts and total percentage of neutrophils do not always run parallel with the infection in the appendix. In view of these observations they believe that the Schilling index in addition to the white count renders a more accurate picture of the pathologic condition of the appendix than the white count with the ordinary differential.

Microscopic Slide Precipitation Test for Syphilis with Spinal Fluid—The microscopic slide precipitation test for syphilis with spinal fluid described by Kline and Rein is said to be more sensitive than the Wassermann test with the same antigen and much simpler in detail, requiring no titrated hemolytic system of cells, amboceptor and complement. Furthermore, it requires no concentration of the globulins of the spinal fluid; it is performed with antigen emulsions that are satisfactory for use for twenty-four hours and the results of the reaction magnified about 120 times by the microscope are read accurately with ease.

Slide Method of Titrating Blood-Grouping Serums—A convenient method of titration of isoagglutinating serums is described by Coca with which the highest titrated serums may be selected as test serums for grouping purpose. A standard of agglutinating power is laid down for such selection. The grouping serums offered to the profession by three reputable commercial biologic houses have been examined and all of them were found to fall below the standard, most of them being quite unsuitable for grouping purposes.

Acute Rheumatic Fever—Clawson states that streptococcal rheumatoid lesions in animals made hypersensitive to streptococci can be prevented by intravenous vaccination. He suggests that this method of vaccination may be indicated in patients with acute rheumatic fever since such patients are hypersensitive to streptococci.

Rheumatic Fever in Childhood—Helmholz stresses the fact that rheumatic fever in childhood may be monosymptomatic or may show a few or all of the manifestations of the so called rheumatic cycle. Complicating disorders of the heart are common and constitute the serious danger of the infection. He urges that all patients with rheumatic fever should have foci of infection removed and should be given a period of from one to two months of restricted regimen. Patients with carditis or chorea should be kept at absolute rest for periods of from six months to a year, after which the normal mode of life may be resumed gradually.

Acute Bowel Obstruction—Wangenstein would label textbook descriptions of intestinal obstruction Antemortem Signs of the Disease. They do not indicate interference with the continuity of the intestinal lumen but herald impending dissolution. Regurgitant vomiting and distention must cease to be criteria awaited before a diagnosis can be made. Collapse in simple bowel obstruction should be relegated to the delineation of that antemortem status in which all vital functions rapidly depreciate and from which escape or resuscitation is unlikely. Intermittent crampy pain accompanied by nausea and considerable vomiting without abdominal rigidity or tenderness, is strongly suggestive of an acute block in the continuity of the intestine. The detection of loud intestinal noises on auscultation of the abdomen and the roentgen visualization of gas in the small intestine, lend sufficient proof to make the diagnosis. The continuance of colicky pain despite the return of gas and feces on the administration of enemata constitutes sufficient indication for immediate operative intervention.

Serotherapy of Measles and Poliomyelitis—When dealing with poliomyelitis, the therapeutic administration of convalescent human serum, preferably in the preparalytic stage of the disease is recommended by Stewart and Platon. For this purpose they give from 20 to 30 cc intraspinally together with 50 to 75 cc intravenously. Furthermore, they do not hesitate to administer the serum after paralysis occurs attempting thereby either to prevent a further extension of the paralysis or to promote as complete a recovery as possible. In the presence of severe epidemics, convalescent serum may be used to afford passive protection to exposed children 10 cc being given subcutaneously to young children and double that amount to older patients. A repetition of the injection at the end of from four to six weeks is suggested should the epidemic outbreak continue in severity for several weeks.

Diffuse Subcortical Sclerosis of Brain—A case of diffuse subcortical sclerosis of the familial type is presented by McKinley clinically and pathologically. The case reports from the recent literature of this and allied conditions are summarized. The confusion of classification and terminology is pointed out.

A simple classification is suggested as follows. The term diffuse subcortical sclerosis is a satisfactory designation for the general group. The subgroups are (1) inflammatory type, (2) familial hereditary type, (3) primary or sporadic type.

Mersalyl as a Diuretic Sixty Cases—Sixty cases in which treatment with mersalyl was used are reported by Sprague and Graybiel. Forty six patients had cardiac disease with congestive failure, eight had cirrhosis of the liver, four had cancer and one each had nephrosis and an ovarian cyst. In spite of the fact that one third of these patients were in the terminal stages of chronic disease, diuresis was secured by the use of mersalyl in 80 per cent. This diuresis exceeded twice the fluid intake in 55 per cent of the cases. Toxic effects from mersalyl are very rare and consist of mild renal, gastro intestinal or skin irritation. The only complication of importance in this series was in one patient who had cellulitis of the arm and thrombosis of the vein into which the drug was given. The authors confirm the opinion of other observers that the drug is an active and safe diuretic, of particular value in the treatment of congestive heart failure with edema of ascites from various causes, and of nephrosis. In some cases it may be useful in treating malignant effusions. It should be used early in the therapy of these conditions and not reserved as a drug of last resort. As a diuretic for repeated use it is useful in its freedom from serious toxicity and almost complete absence of gastro intestinal irritation. Its effectiveness can often be increased by combining it with acid salts, such as ammonium chloride or nitrate, or with other diuretics and digitalis.

Malaria—Knowles and Drs Gupta give details of fifteen cases of benign tertian or of malignant tertian malaria admitted to the hospital, and studied by cultural and enumerative methods. In Bengal, few cases of acute primary malarial infection are seen. Most patients when admitted have had the disease for a month or more and show chronic and 'residual' infections only. The series, however, illustrates the tendency of infection with *Plasmodium* var. to produce a chronic disease associated with relapses and, on the other hand the marked tendency to spontaneous cure in infections with *P. falciparum*. The mechanism of spontaneous cure in malaria is probably associated with the production of lysins in the plasma, with phagocytosis of the merozoites by polymorphonuclear and large hyaline leukocytes and with the activity of the reticulo endothelial system. In Bengal *P. falciparum* infections during September appear to be more closely associated with a large output of gametocytes than do infections in July and August. In 'residual' and convalescent cases of malignant tertian malaria the administration of quinine has the paradoxical effect of greatly increasing the number of crescents in the peripheral blood stream. The administration of a total dose of 0.06 Gm. of plasmochin in six days is sufficient to exterminate the gametocytes of *P. falciparum* from the peripheral blood stream. A suggested standard treatment for malaria is outlined. In this 13 Gm. of quinine is administered in solution in ten days, together with alkalis and 0.01 Gm. of plasmochin daily for the last six days of treatment.

Formation of Rhodan in Body and Region of Formation—Sato describes experiments which proved that the stellate and parenchymal cells of the liver have the function of forming rhodan. The blood of a dog the function of whose liver had been disturbed by sealing of the stellate cells with india ink and by intoxication of the parenchymal cells with carbon tetrachloride and phosphorus and by ligature of the ductus choledochus showed a marked decrease of rhodan after an injection of ethyl cyanide. The stellate and parenchymal cells of the liver of a dog have the function to transform ethyl cyanide into rhodan. A part of the rhodan formed in the liver of a dog is excreted into the bile by means of the stellate and parenchymal cells.

Strength of Immune Body in Artery and Vein—Mitsuse found that there is a substance of complement fixation reactive to the hypoid antigen which is generally used in the Wassermann test, in addition to a specific immune body against cholera bacilli, in the serum of rabbits immunized by cholera bacilli mixed with horse or cow serum. Thus the author tested the difference in the strength of the antibody of the serum in the artery and vein of the animals immunized with the serum. The serum of an artery was slightly more powerful than that of a vein. The immunizing reaction of the serum of a vein was made slightly more powerful by an irrigation of oxygen. The immunizing reaction of an artery was made slightly less

powerful by an irrigation of carbonic acid. Therefore the difference in the action of the immune body of the serum of an immunized animal is due to the difference in the contents of oxygen and carbon dioxide.

| Intestinal Obstruction Due to Ring Cancer of Rectum | E M Fisher |
| — 47 | |

Endometrium and Uterine Hemorrhage—Sutton believes that an understanding of the function of menstruation must be based on a knowledge of its comparative and its intrinsic physiology together with the histology of the cyclic changes in the ovary and the endometrium. Except in the case of bleeding due to retained products, fibroid polypi and carcinoma of the body, irregular uterine bleeding is extra uterine in origin and often extrapelvic, to the latter class belong the metropathoses. Chronic metritis is an infrequent condition associated with chronic interstitial endometritis, the late result of which is true fibrosis uteri. Paraclimacteric fibrosis is only a relative condition and not inflammatory in origin. So called chronic subinvolution is apparently a misconception; it should be termed the parous uterus. None of these conditions usually cause uterine bleeding. They may aggravate or prolong it. Endometritis does not exist except as a transitory condition in the course of an acute severe extrapelvic infection. Before the menopause the uterus is not an organ to be lightly dispensed with because quite apart from its gestational function, it is lined with a complex and ever changing glandular structure possibly possessing, besides an endocrine function, a function relating to calcium economy in the female organism, on this account, when it is subject to hemorrhage not due to malignant growths or large fibroid, due consideration must be given to such procedures as partial hysterectomy or myomectomy with ovarian conservation and roentgen irradiation of the thyroid, pituitary body and spleen. If these procedures fail, the less ideal destruction of the endometrium by radium or surgical diathermy may be practiced.

B.C.G. Vaccination and Vernes' Resorcinol Reaction

—By means of experiments on guinea pigs and observations of children Grysez and Breton ascertained that vaccination with B.C.G. does not cause an augmentation of the optic index of the Vernes resorcinol reaction in fact the optic index rarely exceeds 44 in animals inoculated with B.C.G. and remains below 50 in vaccinated children. Since tuberculin and other tests produce the same reaction in persons vaccinated with B.C.G. as in tuberculous patients the Vernes test gives valuable aid in distinguishing between brain complications arising from the vaccination itself and actual symptoms of tuberculous infection.

Injections of B.C.G. in Animals Infected with Virulent Tuberculosis

—Levitan et al. performed a series of experiments on guinea-pigs, rabbits and monkeys in order to observe the effects of vaccination with B.C.G. on animals inoculated experimentally with tubercle bacilli. While the B.C.G. vaccination proved harmless they noted practically no difference between the condition of the vaccinated animals and the nonvaccinated controls. The guinea pigs and rabbits that had been vaccinated generally lived longer and the tuberculous process seemed to take on a fibrous character particularly in the lymph nodes and in the liver. In some of the tuberculous guinea pigs that were vaccinated, apathy and a slight elevation of temperature were noted after inoculation, the rabbits did not present any reaction of this nature the monkeys had chills, poor appetite and apathy for several days.

Accidents Following Administration of Acriflavine Hydrochloride

—Benard and Tassin report a case of prolonged subacute malignant endocarditis in which one injection of 0.2 Gm. of acriflavine hydrochloride produced a condition of acute hepatic insufficiency with manifestations of cutaneous and visceral purpura; the patient died three and a half days later. They also review the literature dealing with the effects of the acriflavine hydrochloride treatment and find that most authors, even though they testify to the innocuousness of this product, cite one or more cases in which dangerous symptoms were observed after the injections: the most common manifestations being nausea, vomiting, chills, jaundice, insomnia, fever, cutaneous reactions and dysphagia. The authors do not recommend discontinuing the use of acriflavine hydrochloride but they feel that the fact that so many different symptoms have resulted from its use in different cases warrants careful attention to the problem in order to ascertain the cause of these reactions which seem to bear no relation to the quality of the medicament or to the size of the dose administered.

Aqueous Extract of Spleen in Treatment of Pruritus and Eczema

—Chevallier and Bloch report several cases that

demonstrate the excellent results they have secured during the past year by using aqueous splenic extract in the treatment of pruritus and eczema. The extract used corresponds to 125 Gm. of fresh wet spleen per cubic centimeter. It is given in subcutaneous injection. At first the authors injected 2 cc. of the extract every two days. Later they gave doses of 4 cc. every two days. The larger doses in some cases cause a slight fever and general feeling of discomfort. The results of the treatment have never been unpleasant however and the fact that neither diet nor local cutaneous treatment is necessary makes the splenic extract treatment an important therapeutic development.

Treatment of Progressive Chronic Deforming Rheumatism by Parathyroid Extract

—Weissenbach et al. report a case of progressive chronic deforming rheumatism in which subcutaneous injections of parathyroid extract were used with good results. They have used this treatment successfully in about ten cases. The immediate results of the treatment, which manifest themselves after the first few injections, consist of articular flexibility, increased facility of movement, and a feeling of well being. The amelioration appears in from twenty to thirty minutes after the injection, lasts for about twelve hours and then disappears. The authors point out that this temporary amelioration which often permits a patient to resume an apparently normal life is similar to the effects of insulin in diabetes. The late and cumulative effects of the injections of parathyroid extract are also noteworthy: continued use of the treatment tends to relieve permanently the stiffness of the joints and to permit greater ease of movement. While the treatment is of course useless in cases of extreme calcareous and deformity, it is valuable in long standing cases like the one reported in which the patients are confined to their beds and almost helpless. The exact mechanism of the therapeutic effects of the parathyroid extract is not yet known. Since the treatment is so simple however and involves no risk if the patient is given careful attention, the authors recommend its use in refractory cases.

Resection as Means of Avoiding Pulmonary Complications in Gastric Surgery

—Delgémère reports twenty six cases of gastric surgery in which resection was employed; there was only one death which was caused by an embolism. He also gives the results of ten cases in which a simple gastroenterostomy was used and which resulted in three cases of pulmonary complications, two of which were fatal. The author attributes the efficacy of resection in preventing pulmonary complications to the total suppression en masse of the seat of infection.

Comparative Value of Mendel's and Pirquet's Tests in Nurslings

—Because of the recent attacks made on the reliability of Mendel's intradermo test Bernard and Lamy used both I. and Pirquet's test in the examination of 200 nurslings. The results of the two tests proved to be identical in every case. The intradermo reaction was more pronounced than the cutaneous reaction and in the case of infants who entered the hospital

during the antiallergic period the intradermo reaction usually became positive before the cutiraction. The intradermo reaction is therefore to be recommended for use in critical cases. On the other hand, the greater simplicity of technique of the cutiraction is a distinct advantage. The authors state emphatically, however, that they have not observed any discrepancy between the results of the two methods and that Mendel's test is fully as reliable as Pirquet's.

38 1641 1656 (Dec 3) 1930

*Relations Between Contraction of Aponeurosis of Palm and Hypocalcemia and Parathyroid Insufficiency. R Leriche and A Jung—p 1641
*Osteomyelitis Fractures of Upper Extremity of Femur. A Lambotte—p 1647

Contraction of Aponeurosis of Palm and Hypocalcemia and Parathyroid Insufficiency—Impressed by the rather poorly defined but unmistakable relations that seem to exist between the condition of various ligaments and modifications of calcemia, Leriche and Jung determined the calcium content of the blood in two patients with aponeurotic contraction of the palm. In both patients hypocalcemia was present. Injections of parathyroid extract Collip increased the calcemia, enabled the patient to move his fingers more easily and definitely relieved the contraction of the aponeurosis. In view of the facts already established concerning the role played by the parathyroids in relating the tonus of the muscles, the authors consider the results in these two cases of sufficient significance to suggest that disturbances of parathyroid secretion may be either a possible or a habitual cause of Dupuytren's contraction.

Sodium Chloride Treatment in Intestinal Occlusion Following Laparotomy—Bojovitch reports eight cases in which he used intravenous injections of 5 cc of a 20 per cent solution of sodium chloride to relieve intestinal occlusion following a laparotomy. He has also used this treatment as a preventive measure by giving injections of the solution to laparotomized patients ten hours after the operation and every three hours thereafter until normal emission of gas was produced. The author feels that the excellent results secured, together with the simplicity of the treatment justify an extensive use of the method. The effect of the solution seems due to its excitation of the nerves and the smooth muscle fibers of the intestine.

Certain Unusual Indications for Cesarean Section. G Fusco—p 691
Solitary Angiomyomas of Uterus. F Spirito—p 704
*Possible Variation in Iodine Content of Thyroid in Pregnancy and of Fetal Thyroid. G Romaniello—p 716

Unusual Indications for Cesarean Section—Fusco while he admits that his cases are too few to prove anything definitely, is favorable to the view that the indications for cesarean section may well be extended considerably. For the mother, cesarean section may be regarded as not much less favorable than vaginal intervention. For the child, cesarean section is more favorable than the more difficult vaginal operations.

Iodine Content of Thyroid in Pregnancy and of Fetal Thyroid—Romaniello, on the basis of researches carried out on the thyroids of normal and gravid animals and during and immediately following parturition, and also on the thyroids of young just born or several days old, reaches the conclusion that the iodine content of the thyroid increases nearly always in pregnancy, diminishes rapidly during parturition and immediately afterward, and that in the fetal thyroid the iodine does not begin to be found until a few days after birth.

Sulphur and Cholesterol. A Ricci—p 561

*Quantitative Variations of Lipoids and Their Relations in Blood in Experimental and Clinical Anemias. S Marino—p 566

The Quantity of Urea Excreted That Corresponds to a Given Amount of Rest Nitrogen in Blood—Speranza explains his method of calculation that enables him to determine more exactly than with the Ambard formula the amount of urea that azotemic kidney patients should eliminate in twenty four hours in relation to a determined amount of rest nitrogen in the blood and what the deficit of renal functioning is in the elimination of nitrogenous catabolites.

Quantitative Variations of Lipoids and Their Relations in Blood in Anemias—Marino states that the results secured in the various cases examined are worthy of note since, not only in experimental anemias induced by means of pyridine and tolylenediamine but also in clinical anemias the quantitative variations in the lipoids and in their relations, as encountered in the blood point to a disturbance sometimes marked, in the lipid equilibrium of the blood. He was unable however to confirm the importance of the relation of the total cholesterol to the phosphatides in researches on anemias, although some authors have emphasized such importance.

Serous Meningitis—Gandolfi describes in detail a case of serous meningitis that had a long course and ended in a clinical recovery but with the grave sequel of total blindness. The author discusses the diagnosis and points out the difficulties that characterized the onset of the disease.

37 1773 1808 (Dec 8) 1930 Practical Section

The Bacteriophage. G Altana—p 1769
*Significance of Pulse During Childbirth. G Picardi—p 1779

Significance of Pulse During Childbirth—Picardi found bile salts constantly present in the urine of puerperants as shown by the Hay test. In some cases the bile salts were present also during the last days of pregnancy, especially at the onset of labor. Urobilin is sometimes present. This involves doubtless a dissociated icterus caused by toxins of probably ovarian origin. The action of the bile salts on the vagus would explain the behavior of the pulse during the puerperium. It is generally recognized that the nature of the pulse offers one of the most important symptoms for the estimation of the way the puerperium is progressing.

 *Syndrome of Intracranial Hypertension of Syphilitic Origin E. A. Beretervide and E. Delfino—p. 918

Intracranial Hypertension of Syphilitic Origin —

Beretervide and Delfino report the case of a boy, aged 13 years, with congenital syphilis who after an attack of influenza, followed by otitis presented a clinical picture of about a month's duration, constituted by fever, intense cephalalgia, nausea, pain in the neck and motor, sensory and visual disturbances, which proved to be caused by intracranial hypertension. There was no cerebral tumor responsible for the intracranial hypertension, which proved to have a syphilitic etiology. Syphilis may attack the nervous system in a gummatous, cystic, meningeal or pseudotumoral form. As the meningeal form was excluded in this case by the negative results of the chemical and biologic tests any one of the other three forms of syphilis may have caused the condition of the patient. He received nine intramuscular injections of mercuric cyanide. The injections were given, one every other day. The patient recovered and when seen five months later he was still in normal condition. In a review of the literature published during the last six years, the authors found only one case with the same clinical picture and the same characteristics of the cerebrospinal fluid as those observed in their patient. The patient of the previously reported case received antisyphilitic treatment. As the cerebrospinal fluid showed no modifications, the antisyphilitic treatment was discontinued and high voltage roentgen therapy was resorted to. The authors believe that in that case the recovery was credited erroneously to high voltage roentgen therapy. They consider that the intracranial hypertension in both cases (in the case previously reported in the literature and in their case) improved until recovery under the effect of the antisyphilitic treatment.

- *Chronic Ulcerative Colitis of Gastric Origin J. Beretervide and C. T. Carrega Casaffouth—p. 469

Chronic Ulcerative Colitis of Gastric Origin—Beretervide and Carrega Casaffouth say that, in cases of chronic ulcerative colitis in which the studies made at the laboratory give negative results for infection or parasitism of the patient and in which no toxic factors such as uremia, gout or diabetes are involved, the most probable etiologic factor is the insufficiency of the gastric secretion. In cases of that nature a medication directed to improve the gastric secretion in relation to the individual deficiency gives good results. Achylia gastrica is an important factor in the etiology and pathogenesis of chronic ulcerative colitis. The gastric digestion is imperfectly carried out when the gastric juice is lacking in any of its ferments, which condition by itself may cause the gastrogenic diarrhea. The insufficiency of the gastric secretion may also be responsible for many of the symptoms of the clinical picture of patients with chronic ulcerative colitis, by depriving the intestinal flora of the antiseptic and favorable influence that the gastric secretion has on it. The authors report the case of a woman, aged 35, with a grave dysenteric syndrome of chronic ulcerative colitis, which proved to be related to a condition of marked anchlorhydria of the patient. A treatment directed to increase the amount of hydrochloric acid and pepsin in the gastric juice caused the disappearance of the dysenteric syndrome with rapid improvement in the general condition of the patient.**Archiv fur Gynakologie, Berlin**

Calcium Content of Blood Serum During Pregnancy

—Using the method of Kramer Tisdall, Adler determined the calcium content of the blood serum of fourteen healthy nonpregnant women, twenty-six healthy gravidas during the various months of pregnancy, five women during labor and twelve during the puerperium. It was found that during pregnancy the calcium content of the blood serum is below normal and that the decrease appears as early as the third month from the fifth to the ninth months the decrease is uniform. During the tenth month of pregnancy the calcium content of the blood serum is slightly greater than during the preceding month but is still below the normal amount. During labor it increases rapidly to within the lower limits of physiologic variability. The amount of the increase is dependent on the duration of the labor pains. In from twenty-four to forty-eight hours post partum the calcium content of the blood drops to below what it was before labor. It remains subnormal until the eighth day post partum and then rapidly returns to the lower limit of normal.

Potassium and Calcium Contents of Blood During Menstrual Cycle—Spiegler determined the potassium and calcium contents of the blood in fifty women shortly before the appearance of menstruation, seventy-one during menstruation and eighty-three shortly after its completion. He noted that during the menstrual cycle the potassium content of the blood undergoes a marked alteration. As a rule, it reaches its lowest value during menstruation and then increases progressively in the postmenstrual period to reach its maximum in the premenstrum. The calcium content of the blood serum, on the other hand, is extremely stable and does not show noteworthy changes during the menstrual cycle. The opposite behavior of the potassium and calcium ions results in a marked change in the potassium-calcium ratio.

Modification of Alkali Reserve of Blood by Pregnancy

—According to Malfatti and Bartscher, the decrease in the alkali reserve of the blood that occurs in pregnancy becomes more marked during labor. The decrease is greater in primiparas than in multiparas. During the first three or four days post partum the alkali reserve of the blood increases but it does not reach the normal value. Lactation modifies the carbon dioxide combining power of the blood. This modification is manifested by a decrease in the alkali reserve if the blood is withdrawn at least more than twelve hours after the beginning of lactation, if the blood is withdrawn before this time, the decrease cannot be demonstrated. After the decrease in the alkali reserve of the blood which is produced by lactation, there occurs another increase in the carbon dioxide combining power even from twelve to twenty-one days post partum the value has not returned to normal. Septic conditions cause a particularly marked decrease in the alkali reserve. In a case of vomiting of pregnancy and a case of nephropathia gravidarum with a high albumin content of the urine the alkali reserve was decreased below the normal for healthy gravidas.

Antiglycogen Substance in Blood of Gravida —Anselmino and Hoffmann demonstrated in the blood of gravidas a substance possessing the power of decreasing the glycogen content of a mouse's liver. It is present beginning with the second month of pregnancy and increases in concentration during the course of the pregnancy, beginning on the second day post partum its concentration decreases and by the eighth day it has disappeared completely. Its concentration is much less in the fetal blood than in the maternal blood. Two and five tenths cubic centimeters of blood serum from a gravida at the end of

pregnancy produces a decrease of as much as 75 per cent in the glycogen content of a mouse's liver. The substance was identified as thyroid hormone and in its action on the glycogen content of a mouse's liver 25 cc of it corresponded to from 40 to 50 γ of thyroxine.

Influence of Mouth Breathing and Spirography on Pulmonary Ventilation H. Read—p. 121

Curability of Miliary Tuberculosis in Nurslings—Zarfi discusses the high mortality of tuberculosis in nurslings and the particularly unfavorable prognosis of early infection with early generalization of the process. He reports a case of this condition in an infant who was infected with tuberculosis in the first month of life. At the end of the third month tuberculosis of the bronchial lymph nodes was present and by the eighth month there was present an acute general miliary tuberculosis of the pulmonary type with characteristic roentgen changes. The patient recovered both clinically and roentgenologically and two and one-half years later roentgen examination of the lungs revealed only numerous small areas of calcification. Four years have elapsed since the generalization of the tuberculosis. The case is reported as the first instance of recovery of a nursing from acute general miliary tuberculosis.

Sources of Error in Roentgen Diagnosis of Diseases of Lungs—Kremser gives several case histories illustrated with twenty-nine roentgenograms to show some of the common sources of error in the roentgen diagnosis of diseases of the lungs and pleura. The great difficulty in the roentgen diagnosis of diseases of the chest is caused by the fact that the most varied pathologic processes produce the same or similar changes in the roentgenogram. As a result it is frequently impossible to make a definite diagnosis on the basis of only the roentgen examination.

Influence of Mouth Breathing on Pulmonary Ventilation—Read studied thoracographically the influence of forced mouth breathing on the movement of the thoracic wall and demonstrated that a short "transitional reaction" was followed by a reappearance of the rest respiration. Determinations of the carbon dioxide content of the expired alveolar air during and after the mouth breathing revealed that a 'respiratory insufficiency' was not produced by breathing through the mouth. Respiratory experiments with the Knipping apparatus revealed that in most persons there does not occur an appreciable change in the expired alveolar air and in the pulmonary ventilation. In 25 per cent of the cases the carbon dioxide content was increased. Emphasis is laid on the importance of a regular control of the expired alveolar air before and after each experiment.

Investigations on Vaccination Encephalitis—Eckstein et al. report the clinical observations on eighty-six children, aged between 4 and 20 months, who were vaccinated for the first time. They started the vaccinations with four different lymphs, which they had obtained from the vaccine institutions in Berlin, Cologne, Eiberfeld and Dresden, respectively. Twenty-two children were vaccinated with animal lymph and the others were vaccinated with humanized lymph. The pustule formation was

typical even after the lymph had made thirty-six human passages. The fever was milder and of shorter duration in the children who had been vaccinated with humanized lymph than in those who had been vaccinated with animal lymph. However, it would be wrong to infer from this that the immunity produced by humanized lymph is inferior to that produced by animal lymph. This problem the authors intend to investigate by revaccination in later years. Herzberg, Kremmer and Herzberg investigated the pathogenesis of postvaccinal encephalitis by comparing the presence of the vaccine virus in the organism of children with a normal course of vaccination with the occurrence of the virus in children who showed disturbances during the course of vaccination. The results of these tests indicate that the vaccine virus is a causal factor in postvaccinal encephalitis. Accordingly, it seems reasonable to employ human vaccine immune serum for the treatment of postvaccinal encephalitis. The authors further report investigations on the titer of humanized lymph. A decrease in the titer could not be observed even after thirty-six human passages.

Moro's Apple Diet in Treatment of Diarrheal Conditions—Wolff discusses Moro's apple diet, which Moro described in the *Klinische Wochenschrift* (8 2414 [Dec. 24] 1929, abstr. THE JOURNAL, March 1 1930, p. 673). Following a review of the history, Wolff describes the technique of this treatment. He gives special advice for the transitional diet. In all he employed the apple diet in 150 cases. Favorable results were obtained in acute dyspepsia, in dysentery, in chronic dyspepsia and in mucous enteritis. The author describes the clinical histories of three especially severe cases, which proved the great value of the method. Occasionally the diet has to be continued for four days instead of the usual two days. The author asserts that if the diet is properly individualized the results are completely satisfactory.

Albumin Content of Urine in Persons Without Renal Disturbances—The lack of a method by which it is possible to determine the presence of minute quantities of albumin in the urine was, according to Minz, the main reason why it could not be definitely decided whether the urine of normal persons contains albumin or not. The gravimetric methods do not reveal minor quantities. The author therefore employed the nephelometric method, and in order to obtain correct results he prepared a special standard solution. The tests were performed with the aid of an apparatus which is a combination of a colorimeter and a nephelometer. The technique is described in detail. In testing the urines of 100 persons the author did not detect a single one in which albumin was entirely absent. In normal persons the amount eliminated in the urine varied between 0.2 and 0.6 mg. per hundred cubic centimeters. If the average daily quantity of urine is taken as 1500 cc, the quantity of albumin which is daily eliminated with the urine would be from 3 to 9 mg. That the albumin concentration in the urine is not influenced by consumption of large quantities of albumin was demonstrated by the fact that it was not increased after ten boiled eggs had been eaten. The albumin concentration remains the same in the course of a day and some times even during several weeks. However, a tubular report shows that there are considerable differences in the albumin content of the urine during various diseases. In persons with inflammatory conditions the values are usually high. The increased albumin content in hypertension is probably due to a beginning nephrosclerosis. The high values in diabetes

bring to mind the frequent concurrence of renal disorders. It has been repeatedly pointed out that albuminuria is not always a sign of a beginning renal disturbance. However, the author thinks that in diseases which frequently lead to renal disorder a quantitative determination of the albumin in the urine would often make possible an early and effective prophylaxis.

Prophylaxis of Acute Anterior Poliomyelitis—Moro asserts that the observations of numerous investigators have proved that the serum of convalescents has virucidal powers against acute anterior poliomyelitis and that the blood of most adults has the same power. The virucidal action of the blood is mainly due to the presence of specific antibodies. In the therapy, however, the injection of blood from convalescents or from adults has not been effective. This failure is probably due to the fact that the injection is generally given too late. The therapeutic effects were more favorable when the injections were given during the preparalytic stage. However, since it is generally difficult to estimate the disease correctly during the beginning stage, the therapeutic value of injections of blood from convalescents or from adults is minimal. The author, however, recommends injections of blood from adults (convalescent blood is rarely obtainable) for prophylactic purposes. By this method he hopes to prevent epidemics of acute anterior poliomyelitis. Because the children of less than 5 years of age are mainly endangered, they should be given an injection of 20 cc of fresh blood from one of their parents. He thinks that this procedure would give protection for a period of four weeks. If necessary, the injection would have to be repeated at the end of that period. In large cities nearly all adults over 15 years of age have specific protective substances in their blood, and the injection from one adult usually gives sufficient protection. In rural districts, however, only about 50 per cent of adults possess specific antibodies and here it would be necessary to inject mixed blood (from both parents), or serum from adults living in the city could be used.

New Method for Roentgen Demonstration of Liver and Spleen—Radt describes a method which makes it possible to show the liver and spleen as dense shadows in the roentgenogram. The hypothesis on which he bases his method is the following: Certain colloidal substances when parenterally administered become deposited as small granules in the reticulo-endothelial system. Thus spleen and liver become permeated with finest granules. The author reasoned that if a colloid would be used which is impermeable for roentgen rays its deposits in the liver and spleen would produce a more dense shadow in the roentgenogram. Moreover he reasoned that those parts of the liver and spleen (either tissues or fluids) which do not have the capacity to deposit the colloid would be permeable for roentgen rays and the roentgenogram would show differences against the other organ tissues. It could therefore be expected that the method would not only reveal the shape and size of the

liver and spleen but would also show changes within the organ, especially in those cases in which as a result of proliferation the connective tissue had encroached on the parenchymal cells. With the help of this method the author could diagnose a cirrhosis of liver and several times he detected cancerous nodules within the liver. He thinks that it might also be possible to detect abscesses, echinococcus cysts or hemangioma in the liver or spleen. The contrast colloid that was found most satisfactory is a thorium dioxide solution of a certain dispersion, which has been so stabilized by carbohydrates that no body fluid will cause flocculation. The injection is given intravenously. In human beings, from 40 to 80 cc is required. However, this quantity is not injected at once but rather in daily divided doses of from 10 to 20 cc. The injections were never followed by serious complications. Only in a few cases were temporary discomfort, chills and increased temperature noted, but they disappeared quickly. Control of the blood picture revealed a temporary leukocytosis and a slight, likewise only temporary, decrease in the hemoglobin content. Chemical examinations of the blood and urine did not reveal abnormalities. The author made numerous experiments on animals and employed the method on twenty patients. He shows several roentgenograms of patients and comes to the conclusion that this method represents an advance in the diagnosis of disturbances of the liver and the spleen.

Rôle of Liver in Decompensation of Heart—In the first part of the article Zak shows how some parts of the skin are influenced by certain dysfunctions of the liver. With the development of an engorged liver during decompensated circulation, the water depots of the skin become filled. Thus the venous part of the circulation becomes disburdened. The increased avidity of the tissues for water has the effect that the external elimination, namely, perspiration, is reduced, and that is why the surface of the skin is usually dry while the tissues contain large quantities of fluids. Experiments proved the correctness of the clinical observations, and the author concludes that in chronic engorgement of the liver in patients with heart disease there exists a disturbance of the normal relation between the liver and the water content of the tissues.

Newer Methods for Treatment of Bone Fractures—Reduction and fixation are, according to Bohler, the most important factors in the treatment of bone fractures. The reduction is usually accomplished without great difficulty, but the fixation is often difficult. In fractures of the shaft of the forearm in which it is extremely difficult to prevent displacement of the fragments, the author advises that rust-free wires be passed through the bones and then that a plaster-of-paris cast be applied. After the cast has become hardened the ends of the wires are fastened by means of set-screws, which in turn are fastened by a plaster-of-paris bandage. In fractures of the os calcis both reduction and fixation are difficult. Because manual reduction is not possible, a nail is put through the tuber calcanei and a

second one through the tibia, and the fracture is reduced by means of the screw traction apparatus. Then a plaster-of-paris cast is applied. The nails are not removed immediately but remain for from four to five weeks. Medial and intracapsular fractures of the neck of the femur may be treated either by the application of a plaster of paris cast or surgically. In pseudarthrosis of the neck of the femur the author recommends subtrochanteric osteotomy. Beck's method of bone boring he recommends in pseudarthrosis in the shaft of long tubular bones.

Endocrinopathies in Children—According to Massloff, endocrinopathies constitute 44 per cent of all the diseases of children. In early infancy they are characterized principally by growth disturbances and manifestations of spasmodophilia, later, disturbances in the metabolism of fat, water and sugar become of increasing importance. The part played by constitutional predisposition in the development of endocrine disturbances and in the peculiarities of the clinical picture is undisputed. Another important part in the development of various forms of growth and metabolic disturbances in children is played by the central and sympathetic nervous systems. In addition to the purely endocrine disturbances in the growth and metabolism there undoubtedly exist purely dystrophic disturbances. In the investigation of endocrinopathies in children, in the making of a prognosis and in the outlining of the treatment the constitutional factor should be given more consideration than it receives at the present time. Of great importance in the differential diagnosis of the various endocrinopathies are the determination of various indexes and the plotting of the anthropometric curve.

Nutritive and Growth Values of Zwieback—In feeding experiments on rats, Abelm demonstrated that the toasting process which zwieback undergoes after it is baked greatly decreases its growth value. The proteins of flour are poor in several biologically important amino-acids and diamino acids. Some of the growth producing amino-acids, as lysine, are destroyed by the baking and the subsequent heating. This was proved by the fact that the oral administration of extremely small quantities of lysine (20 mg. a day) increased the rate of growth of rats on an exclusive zwieback diet. When the administration of lysine was discontinued, the growth of the animals was arrested. Lysine added to the zwieback dough and then subjected to the baking and toasting process did not prevent the arrest of growth. That the harmful factor is the toasting process rather than the baking was shown by the much better growth of animals on a diet of baked but untoasted zwieback than on a diet of regular zwieback. This modification of the biologically important protein components is more important than the vitamin deficiency. Despite the daily administration of 1 cc. of fresh brewery yeast, of lecithin or of from 2 to 5 cc. of milk, the rats on the zwieback diet did not show a satisfactory increase in weight. The substances with a high vitamin content, as butter and whole milk, which are frequently used in making zwieback, do not give to the finished product a sufficient growth producing action. In young rats that are kept on an exclusive bread zwieback diet there occurs an extensive falling out of the hair. The addition of a minute quantity of dried thyroid substance to the diet arrests the alopecia and stimulates the growth of the hair.

Chlorine in Blood in Scarlet Fever and Diphtheria—In determinations of the chlorine content of the blood in sixty-two cases of scarlet fever and diphtheria, Markowa found that in the early stage of both of these diseases the amount of chlorine in the blood is below normal. The degree of the diminution is directly dependent on the severity of the disease. The cause of

the subnormal chlorine content of the blood in the early stage of scarlet fever and diphtheria is the specific infection and not the accompanying complications.

Incidence of Cancer A. M. Merkow—p. 302

Skin Cancer Production by Prolonged Ultraviolet Irradiation—Putschar and Holtz chose rats instead of mice for their experiments because of the fact that whereas the spontaneous development of cancer is relatively frequent in white mice it is extremely rare in rats. A strain of rats was used in 10,000 of which over a period of three years not a single spontaneous skin tumor was observed. It was found that cancer of the ear could be produced with great regularity without the aid of chemical agents by prolonged ultraviolet irradiation. The carcinomas appeared at the earliest after twenty-seven weeks of continuous irradiation. By the end of the thirty-seventh week, all the six animals had cancer. A definite relation between the color of the skin and the susceptibility to cancer was not demonstrated. The administration of viosterol changed neither the susceptibility to tumors nor their rate of growth. Changes in the elastic tissue in the skin were of a purely retrogressive nature; they did not show any relation to the development of cancer but were a manifestation of chronic ultraviolet ray dermatitis. The specific action of the ultraviolet rays consisted in the production of a periodic regeneration of the hair with a marked increase in the number of lanugo hairs and the development of giant hairs. The authors believe that there exist close histologic relations between ultraviolet ray cancer and the precancerous light dermatoses that occur in man. The experiments prove the etiologic role of ultraviolet rays in cancer of the skin in human beings.

Influence of Sympathetic Nervous System on Development of Experimental Tumors—In experiments on rabbits, Eiger and Czarnecki demonstrated that the sympathetic nervous system has a positive, inhibitory influence on the development of tar epitheliomas. The nutrition also is of importance in rabbits kept on a diet of oats, the development of tar epithelioma is accelerated. The experiments confirm the correctness of the contention of some investigators who consider it necessary to emphasize the importance of precancer.

- Genu Recurvatum Congenitum F. A. Wahl—p. 3265
*Rational Salicyltherapy in Leukorrhea H. Schmidt—p. 3269

Rational Salicyltherapy in Leukorrhea—Schmidt points out that in recent years salicylic acid has been employed in the treatment of leukorrhea. In some cases, however, it has been used in too high concentrations (125 per cent) and the result was that occasionally exacerbations were observed, and many patients complained of burning pain in the vagina. In order to eliminate these disadvantages salicylic acid was used in a 1 or in a 4 per cent solution. It is administered by means of glycerin suppositories, which are introduced into the posterior vault of the vagina. They are melted by the body temperature and the effective substance becomes evenly divided and comes in contact with all diseased portions. The use of glycerin is especially advantageous because of its hygroscopic power, which effects a withdrawal of the cell fluids, so that now, as a result of a reversal of the osmotic pressure a resorption of the salicylic acid becomes possible. Before the use of the glycerin suppositories the effective medicament was frequently discharged again before it became effective. In order to increase the action of

the salicylic acid the author dries the vaginal mucous membrane by means of small compresses before introducing the suppository. If this is done, the hygroscopic power of the glycerin can attack the cells directly, and the 1 per cent solution of salicylic acid is not made ineffective by mixture with the vaginal secretion. For this reason it is advisable that the physician should introduce the suppositories. The author asserts that most cases of nongonorrheal leukorrhea can be effectively counteracted in from eight to twelve days. If the patient introduces the suppositories herself, it is advisable to employ suppositories containing the 4 per cent solution of salicylic acid because the patient does not remove the vaginal secretion. If erosions of the portio vaginalis exist, the 4 per cent solution is likewise advisable. That this treatment has lasting effects is proved by the fact that relapses did not occur, although in some of the patients the treatment was concluded from three to six months previously.

Chemical Study of Manoilov's Reaction—The object of Khromov's researches was to ascertain the influence of hemoglobin on Manoilov's reaction. A 4 per cent solution was prepared with commercial amorphous hemoglobin; then, by adding distilled water to this basal solution a scale of various concentrations was obtained. A dose of 3 cc of a solution was used for the reaction (the third modification method). Only solutions containing more than 1 per cent of hemoglobin proved to influence somewhat the reaction, namely, the coloration pointed then to a female blood. Since solutions containing about 0.5 per cent of hemoglobin are commonly used for Manoilov's reaction, the effect of hemoglobin is not of significance. Evidently hemoglobin does not assume the role of a specific protein. When a higher concentration (more than 1 per cent of hemoglobin) was used, the coloration corresponded to that of female blood instead of that of male blood, as could be expected on account of a larger amount of hemoglobin in the male blood. Thus the hemoglobin acted as a nonspecific protein. Further, it appeared that the results of Manoilov's reaction were correct although identical hemoglobin solutions were used, that is when the difference of hemoglobin contained in the male and female bloods was eliminated. Moreover, blood serum, ascitic fluid, cerebrospinal fluid and urine, which are free from hemoglobin, serve for the reaction. Another series of researches was made with iron protoxides and iron oxides. The basal solution contained 0.558 per cent of iron, it served for the preparation of solutions of lower concentrations. A dose of 3 cc of a solution was used for the reaction. Solutions containing not more than 0.15 per cent of iron proved not to influence appreciably the reaction, with solutions containing more than 0.2 per cent of an iron protoxide, the coloration changed to green or to blue. Obviously there is no connection between the reaction and the amount of iron in the blood, otherwise a solution containing 0.15 per cent of iron would change the coloration to that of the male blood (usually a solution of about 0.0015 per cent of iron is used for the reaction). The results were identical whether a solution of an iron protoxide or of an iron oxide served for the tests. Hence the atomic property of the blood iron is without influence on the reaction.

Influence of Diathermy on Activity of Stomach—The observations of Klyachkin and Mogilevsky were made on forty-two patients with various dyspeptic disturbances. A combined chromoscopic and fractional method was used for exploration of the gastric secretion. The gastric contents were removed while the person was fasting and immediately afterward 2 cc of a 1 per cent aqueous solution of neutral red was injected intramuscularly. Evacuation of the stomach was repeated with the

person fasting, twice at a ten minute interval, and the gastric juice secreted within thirty minutes was examined. Then a caffeine test meal (Ratsch and Kalk) was introduced with a catheter, and the gastric contents were withdrawn every fifteen minutes for about two and a half hours. For determination of the gastric motility, phenolphthalein was added to the test meal. The same procedure of exploration was repeated after the diathermy treatment. One electrode, of from 100 to 150 sq cm was applied to the gastric region, and another electrode, of from 150 to 200 sq cm, was parallelly applied to the back. A current of from 1 to 15 amperes was used, the duration of each sitting was half an hour. Repeated examinations after the treatment were made on twenty-five patients. There were no changes of gastric secretion in three of six patients with hyperacidity. In one the gastric juice secreted during fasting was reduced by 40 cc. In two, the decrease of the gastric juice was by 82 cc, besides, elimination of the neutral red appeared prolonged by three minutes (from nine to twelve minutes) after fifteen sittings of diathermy. In five of seven patients with a normal gastric acidity, the diathermy treatment proved to be without action on the gastric secretion and motility. In one instance the secretion of the gastric juice increased by 64 cc., elimination of the neutral red occurred in twelve instead of eighteen minutes. In another patient the gastric acidity was notably decreased. In two of three patients with hypo-acidity the gastric juice remained unchanged, in the third there was an increase of the gastric acidity and of the gastric secretion (by 54 cc.) and an accelerated elimination of the neutral red. In nine patients free hydrochloric acid was absent and the gastric secretion was notably reduced. In five of them elimination of the neutral red did not occur. In only two cases in which elimination of the neutral red was not entirely abolished did the diathermy treatment result in the appearance of free hydrochloric acid and in an increase of the gastric secretion. In the remainder, no changes were observed after fifteen sittings. These cases of achylia presented a group of 'complete and true anacidity' in which the lesions of the gastric parenchyma were severe. The authors conclude that, in cases of gastric hyperacidity, diathermy treatment is followed by an improvement of the subjective as well as the objective signs. In cases of organic achylia, the treatment had no influence on the gastric secretion but it induced improvement of the general condition and caused the disappearance of subjective signs which had previously resisted various remedies and diets. Therefore diathermy is recommended for patients with dyspeptic manifestations, regardless of the condition of the gastric acidity.

- *Treatment of Colicpvelitis with Bacteriophages C. Nyberg—p. 926
- *Benign Tumors in Striated Muscle G. Tallqvist—p. 934

Treatment of Colicpvelitis with Bacteriophages—Nyberg reports three cases of acute colicpvelitis treated with bacteriophages with good results. He says that in chronic cases it is difficult to find effective bacteriophages, frequently two or more strains of colon bacilli appear in the urine and each of them requires a special bacteriophage.

Benign Tumors in Striated Muscle—Tallqvist affirms that primary connective tissue tumors of myomatous nature occur in the striated muscles. They are usually fibromyomas, and all transition forms between pure myomas and pure fibromas are found. The tumors are as a rule benign. Four cases are described: a myoma, a fibromyoma, a fibroma and a desmoid tumor.

THE CLINIC AS A CENTER OF GRADUATE STUDY *

HENRY A CHRISTIAN, M.D., LL.D. Sc.D.

Hershey Professor of the Theory and Practice of Physic Harvard
University Medical School

BOSTON

"Things in nature rarely are static, they increase or they decrease, they grow or they decay, they progress or they retrogress. Man's education in many respects resembles things of nature, rarely is it static, when knowledge does not increase, almost always it decreases. Physicians should remember this and make every effort to keep out of the static state and on the side of increase, of growth, of progress.

'Physicians can be divided into two great groups, those that are learning and those that are forgetting, those that each year know more, and those that each year know less. There seems no third group, those that are stationary.

"A few physicians increase in knowledge from within and grow from their own doing. These are the innate investigators. The rank and file require outside help to grow and to progress. Books, meetings, contacts, discussions, teachers are our armamentarium for progress. Like the 'spring tonic' of past days, all of us need some of this medicine, at least annually, better if it comes more frequently. A large majority of physicians know their need and seek treatment." Postgraduate instruction is a potent prescription to this end, if it can be carried to the proper dispenser for filling.

Postgraduate instruction should commence with the physician's graduation from the medical school. It should continue throughout his life. Many varieties of postgraduate instruction should be, and in fact are, available to meet the several needs of medical men.

In my judgment the most potent postgraduate clinical instruction in the early period of the medical man's life is afforded by the internship and residentship in a well organized, efficiently run hospital. The medical school curriculum of today really is planned as a preparation for a hospital service. Already many states demand the hospital 'internship' of the candidate for registration in medicine. Graduates of good medical schools with rare exceptions seek service in a hospital following graduation.

The most important influence of teachers in the clinical branches of medicine is not exerted within the medical school on medical students but within the clinic or hospital on recent graduates in medicine. The

clinician's pupils or disciples are not the huge body of his medical students but the small group of his interns or house officers and his residents. To these he imparts the discipline of his leadership. These he conducts in their learning. In the sense of graduate instruction in a university, the resident group form the clinician's seminar. The clinic chiefs satisfactorily fulfilling this function?

Such a relationship is possible only in a clinic organized with a chief of service giving largely of his time and effort to the conduct of the clinic and at heart a teacher and investigator, in a clinic adequately staffed provided with necessary laboratories capable of more than routine examinations, and peopled by not too many patients. The latter is important. The majority of American hospitals have too many patients in ratio to staff and particularly in ratio to resident staff, for them to be significant centers for graduate study. No hospital will attain to the level of a genuine graduate school in clinical branches of medicine, unless it has enough patients to afford numerous examples of disease of many types and enough members of the resident staff, so that each patient may be studied thoroughly and not too hurriedly by one or several of them.

A distinction needs to be made between the graduate study of a clinical branch of medicine and an apprenticeship in one of them. The latter is more analogous to what is known in medical circles as postgraduate study. That there is such a difference seems largely to be lost sight of at present. In industry an apprentice is one who is gradually trained to become a master workman but is not one that is being fitted to be the developer of an industry. The apprentice is taught to carry out the processes of the trade but in so doing he hardly will rise above the level of the average artisan of the trade.

Hospitals in general can easily make of the intern a safe practitioner of average ability if they train him as an apprentice needs to be trained, to do more requires the leadership of men able far beyond the level of the average practitioner and able in different directions. It is the clinic of the latter type, presided over by the real leader, that is the outstanding need of today.

STANDARDIZATION OF HOSPITALS

Present efforts at hospital standardization have attained to a fairly satisfactory level of mediocrity for hospitals. A few, often perfunctory, changes in past practices of a hospital now will secure for it a class A rating. The very poor hospitals have been forced to improve, and this is the only real good that has resulted from all the work of those organizations which have been concerned in the classificatory rating of hospitals. Many institutions, instead of receiving vigorous stimulation to betterment, are basking in the calm complacency of class-A-dom. Regulations of the classifica-

* Read at the banquet held in connection with the Annual Congress of Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1931.
1 From Introduction by Henry A. Christian to the proceedings of the 1930 Post Graduate Assembly.

tionists are cheerfully omitted in the case of the best hospitals in the realization, possibly the subconscious realization of the mediocrity of their standards and the probable deterioration that would result in these hospitals from their uniform enforcement.

If there is to be any official standardization of hospitals, new standards should be set. At present far too many hospitals are rated as satisfactory, that is, the class A hospitals, for such a rating to have much value or to be any real stimulus to improvement. We are too much in the condition of a heaven peopled by perfect beings, the angels. Fewer hospitals should be rated class A than at present is the case, in other words, there should be fewer angels.

In my opinion the fundamental standard demanded of the majority of the hospitals should be that the particular hospital in question be a safe place in which to be a patient. For this it is primarily required that the hospital have the usual modern equipment and that every staff member be a well trained practitioner. The latter is far more important than the former. This would mean the demotion from the staff of any physician who, for one reason or another, does not have the attainments that make him quite safe to care for patients in a hospital presumably equipped to carry out modern diagnostic and therapeutic procedures. This is the most difficult requirement of a classification rating to enforce. Perhaps the fact that it is so difficult is the reason it has played so small a part in present standardization regulations, but it is not in impossibility, with certainty it can be brought about in due course of time. A judiciously placed age retirement rule, which every hospital should have will take care, in time, of all present undesirables, better study of candidates to fill vacancies will reduce to a minimum future incompetents. When a hospital has attained such a staff, this should entitle it to a certain high rating.

All hospitals that are safe places to be sick in within the terms just outlined can be considered as satisfactory for an apprenticeship in medicine, i. e. may be rated as being suitable for internship, provided the staff is willing to devote time to the instruction of interns. In this connection, consideration must be given to what the intern receives in the way of training. The staff must be one that makes a serious effort to train interns. This means, among other things, that the staff members spend a considerable time in the actual examination and discussion of the patients. In many hospitals this is not done, and as a result the intern receives but little guidance and finishes his service without having learned very much.

The type of hospital in which it is safe to be sick, if equipped with modern means of diagnosis and treatment, should be rated, let us say, B, with the possibility of becoming A when these requirements are met in a superlative way. For a long time to come there should be many more class B than class A hospitals.

In addition to such B and A hospitals, there should be recognized another type of hospital, a teaching hospital. Such a hospital should, of course, have all that is needed to be a class A hospital, and in addition some of the staff should be teachers in the broad sense of the word as guides in learning. It is by no means necessary that a teaching hospital have any association with a medical school. In fact, numerous hospitals in actual association with medical schools are not what I would regard as teaching hospitals. Any hospital may become a teaching hospital when members of the staff

follow the general methods applied in graduate instruction in university departments of science and literature. In a teaching hospital there should be a resident staff of several grades, interns or house officers, assistant residents and residents. The resident staff forms the student body with interns as apprentices and assistant residents and residents as graduate students, the latter having considerable free time to carry on investigation.

During the apprenticeship period the service may be a mixed one, though in general a mixed service of any sort with less than a two years' duration affords a definitely unsatisfactory apprenticeship leading to graduate instruction, because a shorter service offers too little time to acquire the routine technique of any one subdivision of the service and may result in the interns becoming a slipshod apprentice. In general, present mixed services are unsatisfactory from a pedagogic aspect and not satisfactory as concerns the care of patients.

THE TEACHING HOSPITAL

As in any other scheme of graduate instruction, leadership is far more important than material facilities, and it is in real leadership that our clinics are weakest. In a teaching clinic the leadership of the chief of service looms large in the success of the clinic in graduate instruction. It is exceedingly difficult to specify the criteria essential for such leadership, and if one reviews the lives of men who have had great accomplishments to their credit in these lines, it is obvious that there has been much variation both in their personality and in their methods.

No better examples of this can be cited than in the case of William Osler and William S. Halsted while leaders, respectively, of the medical and surgical clinics of the Johns Hopkins Hospital. If my readers did not know personally these two great leaders of a comparatively recent date, they should read Cushing's *Life of Sir William Osler* and MacCallum's *William Stewart Halsted Surgeon*, to see how entirely different these men were in personality and methods, while each was the head of a noteworthy school of graduate study of clinical branches of medicine. Something of Halsted's point of view is given in a letter to one of his assistants in the following sentences:

In the building up of a school you will have to sacrifice yourself to the interests of the school and of your assistants. This, in itself, is a fine perhaps the finest ambition. And you will be the only one able, even approximately, to estimate the extent of the sacrifice and the effects of the impress of your suggestions and teachings and example. The head of a department in a school should give his problems freely to his assistants (and I have been happy to note that this is your tendency) rather than to technicians and skilled students and assistants, the results of whose work would redound to his glory.

Again Halsted writes:

We wish men who have learned to work for work's sake, who find in it and in the search for truth their greatest reward.

The success of graduate instruction can be judged best by the type and number of the pupils, and their subsequent careers. Former pupils more than any others should influence one in the selection of a leader under whom to seek graduate instruction. "The worth of a professor is measured by the personality of those whom he has trained" (Leriche). My advice to one seeking such an opportunity for graduate instruction in clinical fields would be to study the history of, and, it

possible, to interview former members of the resident staff of a given clinic and to judge of the leadership of the chief from the quality of those that have come under his leadership.

EXTENSIVE VERSUS LIMITED KNOWLEDGE

It would seem an almost necessary qualification that the chief of a teaching clinic should have a broad grasp of the entire field of his clinical endeavor as well as a special knowledge of some particular subdivision of the field. He should be a clinician of wide experience and one steeped in the literature and lore of his domain in medicine. He should be familiar with the methods of investigation and have some accomplishment in investigation to his credit.

In recent years I have been wondering whether much of great significance has not been lost in the trend toward a narrowed devotion to some particular phase of a given general field of medicine. Are we any longer what I would term scholarly or erudite in medicine? The younger leaders in some of the best clinics have specialized in securing their training by an intensive study of some relatively limited field and then clinics are so organized that only this same sort of training is being afforded to their associates. I would not decry such intensive investigation, but I wonder if it would not be wiser to organize the clinic so that each in turn would have contact at times with the many varieties of disease that without the limitations of selection, seek the care of any larger clinic and at other times would study intensively a selected group of patients with some special sort of departure from normal. Should not our teachers know much of many different varieties of disease processes? How else can that be attained than in the personal study of many patients of many sorts and continued reading of a wide range of medical literature. Certainly for adequate apprenticeship training in the first period of hospital internship, contact with a general rather than a special type of clinic is essential to proper training. How may that be attained, if the clinic is broken up into subdivisions for special study with each intern and resident attached to a special group as so generally is the organization of clinics of internal medicine in the United States today?

Too often, it seems to me, I hear it said that nowadays medical literature is so vast that no one man can keep track of all of it. That medical literature is vast is true, but is that idea not too often used as an excuse for reading in only a narrow field, when really one is but excusing an inborn laziness that makes him shirk from the task of reading as much in various fields as it is possible to do? The result is that younger clinic chiefs generally seem to lack broad knowledge of their subject, and their teaching and leadership is, as a result, narrow and one sided, far more than it should be.

NEED IN THE CLINIC FOR SUSTAINED INVESTIGATION

As one looks about, the men most competent for sustained investigation now seem to be turning to the preclinical sciences rather than entering the clinics. Several factors, it seems to me, are working to that end. Clinic chiefs are tending to become limited in their knowledge of medical literature and familiar with a narrowed field of clinical observation. The many clinics enlarged and reorganized in recent years have offered many attractive positions to younger men and this has stopped that long sojourn in preclinical fields so commonly practiced by our predecessors in clinical

fields. The result is that few present-day clinicians have had prolonged contact in preclinical laboratories with the master minds in these fields. They have missed a most valuable training and discipline which then work in the clinic with its diverting interests and necessities incident to the care of patients has failed to supply. In the clinics, students are coming under less notable leadership than they would have had in the preclinical sciences. In organizing our clinics we have failed to secure the opportunity for mature, sustained investigation. Clinical problems are being investigated but few clinic heads have the ability for sustained investigation of related problems and, if they had, then numerous other duties would allow them no time for such type of work. Clinic chiefs, as we have them are needed and they fill well certain requirements of the clinic. No clinic can care for its patients satisfactorily unless it has a truly large group of clinically mature men and these have an important role to play in the teaching within the clinic. There is a need however in addition for the development of another type of clinic worker, the one whose great interest in life is investigation. Such men should have coordinate rank and remuneration with the present type of chief of clinic, the two types should work side by side. At present almost all that is offered as a reward to the former is the opportunity to become the latter type with duties that almost surely will preclude continuation in the endeavor that has won for him the right of reward by promotion. Lack of such opportunity to attain to positions of permanence and dignity with adequate salary is a deterrent to the man with a serious interest in sustained investigation from continuing in the clinic though there he may find problems of great interest to study.

It was this lack in the clinics of the past that was an important influence in the development of so-called whole time teaching in clinical branches of medicine. Whole time teaching with its artificial restrictions pointed the way to improvement and now the artificial restrictions are being abandoned largely because they are obviously artificial. The newer clinics are better but they seem little nearer to the investigational idea of a true university department of graduate study. This is being recognized in many parts of the world and new methods will be tried toward this end of more sustained, higher grade investigation within the clinic. It is with the hope that here in America the solution may be found that I have called attention here to the matter. Perhaps it is not possible, for the present to get any further than to realize the lack and to feel the need of the truly investigative aspects of the discipline of clinical branches of medicine. However that accomplished, an important step has been taken. University education has been going through attempts to solve similar problems, and they seem to have advanced further than have the clinical branches of medicine. This but emphasizes the greater difficulty in clinical fields, where the needs of patients are of first consideration. The more difficult problem should be but a challenge to greater effort. The problem certainly is not insoluble.

EDUCATION OF NURSES

Now, may I turn my attention briefly to nursing education, nursing service, in relation to what I have just been discussing. Please realize that I am speaking as one who never has had any direct contact with the problems of educating nurses but rather as one who in a life spent almost continuously within the walls of a

hospital has watched with keen interest how the product of the school of nursing has worked in the care of patients and cooperated in the investigation of clinical problems concerned with the study of patients. I say advisedly that I have had no direct contact with the problems of educating nurses, for in a service of eighteen years as physician-in-chief of a general hospital, I can recall no occasion on which the advice of the visiting staff of the hospital has been asked with regard to the conduct of the hospital's training school for nurses.

Viewed from such an outside position, to me the education of nurses, with rare exceptions, is entirely that of an apprenticeship in which the nurse learns, largely by doing under guidance the various maneuvers of the care of the sick with a modicum of instruction in the fundamental background of a knowledge of medicine. Here and there a graduate of such an apprenticeship enters on what may be termed a course of graduate study in nursing or some topic related to nursing problems.

To me this sort of apprenticeship seems the correct method in general for the training of nurses, except for those who are to participate in the instruction of nurses and in the guidance of their schools. It is the trained apprentice that is needed in the nurse and I may add the intelligent apprentice. At present in most training schools the attempt is being made to interweave into the practical apprenticeship the needed education in the underlying principles. For the physician in charge of patients this is not proving especially satisfactory, also I am told that for those interested in nursing education there is dissatisfaction. To me it would seem far more satisfactory if the nurse completed her nursing education, including instruction in practical nursing and then came into the wards for a period of apprenticeship in much the same way as at present do the interns after they graduate from the medical school. Perhaps a twelve months period of work of this type in the hospital wards would suffice, if it follows a thorough course in a nursing school. This arrangement would necessitate the hospital providing more graduate nurses for the care of patients, a movement already under way and one in every way desirable from the side of the professional staff of the hospital.

Under present conditions the nurse, to get her education, is constantly shifting from ward to ward and even from hospital to hospital with the result that too many persons become responsible for the care of the individual patient in each twenty-four hour period for the patient to get a genuinely satisfactory nursing care. As I see it, hospital nursing by student nurses is not as satisfactory as it was five or ten years ago, so far as concerns the care of the patients and the making of needed observations on them. This results in part from present methods of training nurses and is in part the result of a general change that has been going on, which has resulted in getting into training for nurses a less seriously responsible type of girls, no longer capable or willing to carry out meticulously every detail of the plan of treatment or investigation of the patient, a change that my friends in the business and industrial world tell me that they, too, observe in their personnel. I believe the time has come to separate the training school for nurses from the hospital as already has been done for medical schools. I see no reason why the training school should be a cost on the hospital funds, rather should it be financed as are other educational projects.

PRIMARY IMPORTANCE OF CARING FOR PATIENT

It is to be remembered always that the first concern of every hospital should be the best possible care of the patient. Nothing, however advantageous for the education of physicians or nurses, should be tolerated if it detracts in any way from the effectiveness of the care of the patient in the effort to mitigate his discomfort and to speed his recovery from his sickness. Those concerned primarily in the educational aspects of the clinic must have this constantly in mind, those concerned primarily in the care of the patient must see to it that it is done, provision must be made for the professional nursing care of the patient so that his care may reach the highest possible level of efficiency and effectiveness.

MENTAL HEALTH AS A NATIONAL PROBLEM*

RAY LYMAN WILBUR, MD

Secretary of the Interior

WASHINGTON, D. C.

Probably one of the highest compliments that can be given is to say that a man has good common sense, or to say that the people of a nation are sane and stable. All recognize to some degree the eternal conflicts between the emotions and the intelligence. These conflicts may be seasonal. They are associated with certain periods of life and they are fundamental in determining one's happiness, achievements and personality. From a national standpoint there is the most persistent evidence of the interrelations and interplay between intelligence and emotions.

Human behavior in the mass determines our successes or our failures as a nation. Politically, many of us at all times, and all of us at some times, act like the proverbial college sophomore. As an observing senator has said: "Our greatest safety is our organization by states, for not more than a dozen states are apt to go haywire at the same time."

Whatever we may do or whatever we are is determined by our nervous systems. Some one years ago, described what he called the "cerebrospinal parasite." He gave a picture of a few cells folding in at a certain time from the surface of the growing embryo and gradually through the growth and the extension of associated cells and fibers gathering control of the rest of the organism. The brain can be viewed as a colony of highly specialized living cells controlling practically everything that one does and yet dependent on the quality of the body juices for its safety and readily affected by the secretion of various glands, by toxins of various origin, by temperature, and by a host of other conditions. It may be a disturbing picture to think of the brain as immersed in fluids the character of which largely control its activities, but such is the case. Consciousness, will and personality defy accurate understanding. They are a part of that fog of mystery and mysticism that permeates everything human. We cover our ignorance with long words and by explanations that are largely descriptive. We do, of course, know a great deal about ourselves and about others, but when we think in terms of the mental health of a nation we are impressed by the variability in human material and by the accidental happenings that may determine the birth, growth and value of any single individual.

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1931.

A noble personality residing in a superb physical body may be completely changed by an attack of meningitis, by the use of drugs, by the gradual effects of some early disease on the blood vessels of the brain or the kidneys, or by the overactivity or underactivity of various glands. A sudden accident may transfer a person in a moment from stable self-control to tottering and failing mentality.

We know the wide range of variation in the capacity of individuals as regards both their physical aptitudes and their mental qualities. Just at present there have been so many changes in environment and in human requirements that we are conscious that we have passed through a stage of human labor when hands and legs were all that were needed to that of the brain and machine control of work. Our social set-up must always make provision for a large number of brains of inferior or very moderate capacity, while at the same time we must deal with those at the top and those who have extraordinary ability bordering on genius. The gap between special abilities and genius and those deviations of the mind which is called insanity seems to be very narrow. Aside from those who would be definitely labeled as mental cases there are many whose minds have a moderate twist up to half a turn. Any one in public life who receives a large "nut" must be conscious of the high percentage of cranks in our civilization.

We have to view ourselves and our neighbors as possible mental cases at some future date. As I have indicated, the incidents of disease or of accident may be determining factors, but the war demonstrated the unmasking effect of emotional overstrain.

Heredity is a persistent factor that cannot be lost sight of in national mental health. I suppose that the fact that every baby falls on his head has been of inestimable value in the comforting of parents and relatives when mental weakness or disease appeared in the family. There is little that can be done about heredity after life has once started. There is much that might be done if intelligence rather than emotions controlled the quality of the oncoming race. The blending of the various diverse elements making up the population of the United States is producing millions of individuals with certain definite traits. It is evident that this continent is an admirable place for us. There are but few difficulties in our environment that cannot be overcome by the applications of science in the fields of public health and community and industrial organization. We seem likely to go forward as a people for many centuries so far as the physical possibilities are concerned. The great question as we look ahead is "What kind of people are we to be from the standpoint of the mind and of behavior?"

Democracy demands at least a majority of self-maintaining competent citizens with orderly, cooperative habits and with balanced, temperate minds. The demagogue has always found some soil for his sowing. Disaster awaits any people with too high a percentage of the insane, the mentally defective or the emotionally unstable. Trouble stands at the door of any people who are not partially immune to sophistry. In sanity lies safety.

At the present time much of our care of those who deviate too far to the abnormal is that of simple capture and control. When once evidently established we try to classify our mental cases, treat them as well as we can, and live in hope that the difficulties will pass and the normal personality reappear.

We have done comparatively little in the way of prevention. Mental hygiene is now becoming a word with which we can conjure. It seems to me that with the increasing interest in each other which is compelled by our present economic and social organization, we are in a position where we must look to the safety of our future. Certainly we do not want to think of a period in which a considerable minority of our population is either living in institutions or entering or leaving them. We now talk in terms of millions in connection with mental diseases. At the same time there are certain changes in our attitudes and information that are hopeful. We are beginning to think of mental and physical disease in common terms. We have much less prejudice toward the insane, although certainly enough of it still exists.

The protection of the family given in the past to the imbecile or the mildly insane is now insufficient. A family living on a large farm could stand an occasional melancholy maiden aunt or an hysterical adolescent, a drunkard, an epileptic, and could find some use for even a reckless and unstable man. But we are now too close together to meet problems of this kind in this way.

The diseases in which the brain is involved are similar to those in which other parts of the body are involved. Simple recognition of the fact that mental sickness is simply another form of sickness would be of inestimable importance. Along with this growing change in sentiment, science has modified our conceptions of our environment so that ghosts, devils, imps, are joining the dodo bird in that limbo to which humanity sends its outworn conceptions or its relics of what has gone before.

What can we do to strengthen the mental health of the nation? In the first place, we must have trained men and women who know as much as can be known about psychiatry, and we must have every physician trained so that he will have an adequate conception of the various mental states. The profession of medicine has been so engrossed with its marvelous successes in the application of biology, physics and chemistry to the protection and treatment of human beings that it has paid little attention to psychiatry and to the mental side of patients. Certain experts have developed more or less by chance, but deliberate preparation of the medical profession in psychiatry has been in this country, for the most part, and in other countries as well, of a distinctly inferior character. This troublesome mysterious and difficult domain of health must be studied and restudied. As we conquer infectious diseases, as we prolong life, the necessity increases for us as physicians to assist in the living out of life under what we call modern conditions.

Happiness and something to do seem to go together. The intricate divisions of labor that have gone on in society require that this something to do shall be prepared for in an adequate manner. It is important for each one to find that particular niche which is appropriate to his particular capacities. A majority choose their occupations by accident and chance. Most of us do not know where our capacities lie. Some of those whom we value most during war give us the most trouble during peace. Some men seem to rise to highest honor in war or emergency, in peace they wreck themselves. Education is of the greatest value. Through it we can unfold the mind and its range and gradually find a place for each member of modern society.

there are physicians, few and far between, who are doing that very thing

The reason for this discrepancy lies primarily in defects of medical education. In the May, 1930, issue of the *American Medical Association Bulletin* the cover page contains a statement by Glenn Frank on "What the Great Doctor Must Know." In brief he said

The great doctor must know almost as much about the social order as the sociologist. This is necessary because the varied forces—political, social, economic, industrial, educational, religious—that march across a nation, making its mind or marring its spirit, register their effects in the lives of the doctor's patients. The more the doctor knows about these forces that make the atmosphere in which men's minds and bodies live the more intelligently can he trace effects to their causes, and the more wisely can he counsel his patients.

The great doctor must know almost as much about the mind as the psychologist. This is necessary because even the most materialistic scientist admits that there is a subtle relationship between mind and body that the doctor of the body dare not overlook, for when he does overlook this relationship a thousand quacks rush in to capitalize his oversight.

The great doctor must know as much about the subtle art of counseling as the priest.

How much have we, representing American medicine, done in medical education to achieve that goal? The chief reason why the community clinic has not found a greater ally in the community physician is that the medical student has been so lured along the easy path of monogenesis of human ills. Thinking in terms of unitary causations has been a much easier thing in general medicine than in psychiatry and we find the medical graduate so case-hardened that only rarely can he break through in his etiologic thinking to achieve a polygenic concept. The extent to which the neophyte in psychiatry clings to now heredity, now focal infection, now endocrinology, now an Oedipus complex in spite of the fact that multiple causations fit in his face constantly, reveals how constricting are the pathologic concepts fed to our medical students and how lost they become when the patient requires a consideration and balancing of several causations. The release from barren cryptic diagnostic formulations leading along single paths to inadequate prognostication and therapy has been a boon to the psychiatrist that may be carried over with profit to medicine as a whole. Only when something has been achieved along these lines can the community clinic and the community physician find a real percentage of value in their cooperation.

I do not want it to be understood from what I have said that community clinics have not found the physician friendly, interested and appreciative. He has been that and more. What I mean is that he has been shackled in a way that hampers the most valuable expression of his friendliness.

As I have indicated, there are others who have been interested in man-as-a-whole. Foremost among these others is the school teacher. Trained in different sciences and techniques and still legitimately concerned with mental health, the clinic and teacher have often battled over supposed trespassing on each other's ground. No community mental hygiene clinic can approach its goal without active participation by the teacher, and the mutual understanding with allowance for a fairly broad overlap is essential to cooperation. Her participation may be summarized by saying that she must practice pedagogy at its best and be one with the clinic when the problem with which she is faced

exceeds in complexity and severity the bounds of her class room and the specialized pedagogic services while the psychiatrist assumes a corresponding attitude. Such cases ideally will be relatively few, but actually the teacher has been just as much case-hardened as has the medical student. On the other hand, there is a very visible tendency, certainly more visible than with the medical school, toward a lumbering of teacher training. The community clinic is insuring its own salvation by participating in this lumbering process.

Community clinics originally linked up very closely with the work of the juvenile court. Some of our most important progress has come from this linkage. The most serious obstacles to greater achievement have been the traditions of penology and the inability to free the whole system of probation from political domination. Only rarely has the work of the juvenile court judge or his probation department, if such there is, been built on the philosophy which dignifies a profession. Where this has been achieved as now and originally here in Chicago, the community clinic and juvenile court working as a unit render a service which respects fully the highest ideals of psychiatry and criminology in their public health or preventive aspects. This originally independent handling of the problem of man-as-a-whole by the physician and by the court has been brought together in mutually strengthened cooperation rather than in the noisome conflicts between psychiatry and law that all too frequently mold public opinion.

The community clinic has found that its greatest ally, the one that could cooperate most readily in its case studies and case treatment, has been the social agency. On the average, far more attention is paid to the dynamics of human behavior in training the social worker than in the training of any other profession, including the physician. I would not say that the social worker graduating from what are comparable to grade A schools is better trained in psychiatry, but many a medical school could trade its specific psychiatric course for that part of psychiatry given elsewhere to social workers and gain immeasurably by the exchange. Much of the development of community clinic work has come about because the social worker sees the role of human dynamics and psychopathology in her cases and is unequipped to go further or is sufficiently prudent to abide by the bounds of her guild. True it is that she will have to be equipped even more than she is now before she can reach a point in case work that will leave a balance of more complex cases reasonably approaching in smallness the capacity of a community clinic. Her growth toward this ideal should be slow and deliberate, but even then it will have to wait for medical education, judging by the present speed of progress.

With the public health nurse, the minister and a host of other people dealing with the life problems of human beings, problems more or less dependent on peculiarities of anatomy and physiology as well as of human experience and social structure, the community clinic forms a functional linkage. A man in trouble does not divide his problems and experiences into categories for the judge, the physician, the teacher, the social worker and the clinic. His problem is a unit to him, it is one problem with many connected phases. It is indivisible, and when he is divided up among several professions for repair, the efforts just do not take.

In order to translate some of the foregoing generalities into concrete activity, let me follow through the functions of a clinic group on a case handled coopera-

tively with a social agency This pattern will be rather generally applicable

Here is Miss Allen, a case worker in a family welfare agency In meeting the problems of the Russo family in the tenement district she finds that 11 year old Tony is doing poorly in school, is constantly picked on by the other boys, or else sullenly keeps so apart from the group that his development is being seriously brased Miss Allen sees the probability of a psychiatric problem which calls for special help Knowing clinic routine from past experience, she makes a detailed study of the past records of the Russo family, amplifies this by some special examination of the family picture and school setting, and presents this social examination to the clinic with her report for its participation The clinic grants this request, the psychiatric social worker of the clinic, Miss McKay, reviews the report of Miss Allen and advises perhaps certain amplifications, which are then secured Tony is next examined by the clinic psychiatrist, physically and mentally, and the psychologist makes ratings of Tony's intelligence and other capacities This completed, all the participants gather together in what is called a staff conference, they present their observations, points of view and interpretations, reach an understanding of their differences, and come to a single picture of Tony's problem They decide what they should do in order to achieve healthier results Certain of these treatment jobs are of social manipulation, others psychotherapy, others deal with correction of physical defects and others with school difficulties Miss Allen takes responsibility for the social manipulation and goes back to her agency with a distinct job, yet a job correlated with and moving along with a larger plan The clinic keeps in as close touch with her work as if it were on her staff and vice versa Miss Allen has other cases which might benefit by clinic service but these are so numerous that only Miss Allen can handle them She may get direct or indirect help on some of these from the clinic in various ways Similarly the clinic comes to a better appreciation of certain family problems and their treatment So much for this pattern of cooperative relationship

Suppose in place of Miss Allen there is a probation officer, a child adoption agent, a teacher, a school psychologist, a visiting nurse or a family physician or psychiatrist It is evident that each of these in his own line can participate cooperatively in the work of the clinic and find the accessory services for a practically complete study of his problem case It is evident that his routine problems will be so many that he cannot always resort to such service but will have up to a certain point usually to depend on the building up of his own capacities

Community clinics, however, are not to be had for the asking They cost money, much money, \$20,000 or so for a full time service Furthermore, even with money assured, personnel is hard to get When one considers the smaller community, roughly under 200,000, the prospect of developing such a service is scant Money is too limited, attractions to the staff are too meager Such communities constitute about 80 per cent of the United States In such cases one has either to look to some fortuitous circumstance or else to such existing services as are conducted by state departments of health, mental hygiene, education or welfare, and universities Much of the progress of the future may be expected from the assumption by state hospitals and universities of the community responsibility for mental

hygiene through the conduct of part time community clinics

There is one point that must be appreciated however, in the furtherance of a community mental hygiene program through a clinic, namely, that, large or small, such a clinic can be fitted to a community only through careful study of that community Its structure (schools, agencies and courts) and its functions (traditions, laws and other elements) giving a distinguishing atmosphere Its pathologic changes, dysfunctions and defects have to be gone into just as one might do for a patient The community is a patient that wants help To provide such help requires group diagnosis and the willingness of one specialist in social organization to see his work in its proper relationships even though this means a disappointing delay in his opportunity to contribute to the therapy Mental hygiene more often than not has to step aside until some grosser disintegrating community defect in welfare, health or education is attended to Only in this way can a community clinic achieve a balanced function in community mental hygiene

Even after its establishment in a community with a fairly high level of work in its various mental hygiene fields, the clinic has constantly before it the opportunity through its cases to point out wherein the community needs changes in its social services, education, recreation, health and industrial planning Every case seen by a clinic presents, in addition, lessons which may be carried over to the adults concerned with the case The community clinic, in addition, uses its materials for professional training "Case" in a community clinic means not only an opportunity for therapy, it becomes, also, and sometimes with greater value, a medium of community education and organization, and a problem for research

SUMMARY

The mental hygienist in developing his preventive and early treatment program is confronted with a more complex situation than the physical hygienist in that his subject, man-as-a-whole as contrasted to his parts is a freely moving agent which is constantly changing its relationships and inducing responses from people on a variety of grounds Prevention in mental hygiene work hence has been sought not only in medicine but also in criminology, social service, pedagogy and religion and a successful community effort must coordinate these varied approaches Mental hygiene, consequently, depends on the willingness and capacity for cooperation of a number of co-equal groups no one of which can assume too much authority This entails an extensive improvement in professional education so that the teacher will teach better, the social worker and public health nurse will do their jobs better, the judge will plan better for his cases, the minister will guide better, and the physician will see his problems with their broader implications This last means a new shading, not an added subject to medical education The mental health activities of a community cannot get ahead of these advances in professional training The clinic can provide service to the few cases whose mental hygiene needs exceed the capacities of other agencies in the community it can shoulder the jobs of others only temporarily and pending the development of these capacities Beyond clinical service it carries a responsibility for community education and organization The mental hygiene of a community is a compound whole community job in which the clinic provides leadership and a limited specialized service

450 Seventh Avenue

THE RÔLE OF THE STATE HOSPITAL IN MENTAL HYGIENE*

J ALLEN JACKSON, M.D.
Superintendent Danville State Hospital
DANVILLE, VA.

In reviewing the care of the mentally ill and the fundamentals of the mental hygiene movement to wit, the prevention, diagnosis and treatment of mental illness, one notes a definite role that the mental hospital has always played and always will play in the movement a role that will not be effaced but, on the contrary, will become more prominent with the passing years.

The role of a research and treatment agency cannot be denied the mental hospital of the past. The great mass of knowledge on mental hygiene now possessed came through such institutions. The part played by these institutions in the broader fields of prevention, through mental clinics, social service and educational activities, in more recent years likewise tends to fix them more permanently as the keystone in any physical organization for the practical application of mental hygiene. In rural districts, particularly, these institutions have become such integral parts of organized community mental hygiene forces that there are those who have a strong conviction that the rural mental hospital should be the logical mental health center of a rural community and as such should lend its building program, personnel and administrative policies to this end in order to assume its logical leadership. Furthermore, they realize that this can be done in such a way as to harmonize with such policies, rules and regulations as might be laid down by central boards of control, welfare departments or state commissioners of mental hygiene.

The mental hospitals of urban districts are likewise playing their role. However, one can sense the necessity of having to harmonize these institutional programs with the local municipal departments of health as relates to clinics, to the consideration of specialists in psychiatry who abide in such places for the pursuit of their profession, to the many social agencies and to the educational institutions. I believe that many such institutions are lending their efforts to this end but, owing to the many dovetailings of the activities with other agencies in the urban districts, the activities are not as clear cut as those of the hospital in a rural district in which the fields are meager so far as social agencies and psychiatrists are concerned.

Merely stating a proposition without foundation or fact carries little weight other than a suggestion. It remains therefore, for me as the essayist to present for consideration in outline of the organization, administration and results of the mental hospital in its role in the mental hygiene movement that would substantiate the statement that the mental hospital is one of the basic keystones in the physical organization for the promotion of any community, city, state or national mental hygiene program.

First and foremost, I should ask that the field to be covered and the geographic location of the mental hospitals to this field be borne in mind. These institutions are so situated as to serve both city and rural districts and, with the exception of a few hospitals in the larger

cities, all are in rural districts. The so-called urban hospitals, in addition to serving cities, also serve additional counties of rural make-up. Furthermore, I think that everyone must agree that in the rural fields lie the greatest obstacles to a practical application of a mental hygiene program if there are no mental hospital activities. For example, there are no psychiatrists and few if any community health organizations, while traveling mental clinic contacts are too infrequent and unsatisfactory. The cost of child guidance clinics in these areas makes their use prohibitive. The educational institutions are in many instances lacking in professional personnel for the examination of school children. There are no available psychiatrists for contact with the normal schools, colleges and universities. On the other hand, if the mental hospitals are utilized and with but little additional expense adequate community service departments are organized, far reaching will be the influence of these institutions. Such a department can provide mental clinics, the examination of school children, lectures for colleges and universities (with hospital visitations) and talks to various service clubs, as well as health news to the public press and visitors to the hospital. It is also possible to publish a mental health bulletin quarterly for selected readers in the hospital district.

The field to be covered, the facilities at hand, the cost, the consideration and the results obtained are the guiding criteria in the field of business and must necessarily be considered in mental hygiene activities. My own experience has been that utilization of the mental hospital with cooperation on the part of the community in providing some small expense, quarters, and utilization of their regularly organized forces gives the best and least expensive facilities and covers the field more thoroughly and with more satisfaction to the community than other types of approach. In the larger cities, other agencies might be utilized to a better advantage and the city mental hospital relegated to a purely custodial and treatment institution. My convictions are, however, that these institutions, as those in rural districts, should become a very vital part of the mental hygiene program.

As I have indicated in a preceding paragraph, in the event of either a rural or an urban mental hospital entering the field of mental hygiene, there are certain fundamentals that these institutions must possess, namely, physical structures, personnel and adequate administrative programs. It is needless to say that, first, these should harmonize with the advanced thought of mental hygiene as relates to prevention, through clinics and education. Secondly, there should be proper units for research, and observation of borderline cases, sections for the treatment of the acutely ill those requiring constant hospital care and supervision for colony supervision and for diseases of an infectious nature. Furthermore, I believe that the patients treated should be restricted to those suffering from neuroses, psychoneuroses and true psychoses. A large number of admissions of idiots, imbeciles, epileptics, juvenile delinquents and feeble-minded obstruct the progress of a true mental hospital. Fortunately, in Pennsylvania, individual units for each class have been begun and the day is anticipated when the mental hospitals will be purely for the type of patients enumerated. In conjunction with the physical units there should be all the necessary scientific, research, laboratory and treatment facilities, the latter including the various therapies.

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1931.

Second in importance is the personnel, headed by officers, physicians, executives, skilled business men and artisans of trade of the best training and personalities. A training school for nurses is essential, as well as the special therapies. In both the professional and the business side, the activities should be so grouped and checked as to warrant a continuity of service. Definite programs of business should be insisted on. Definite professional programs of psychiatric conferences, physical diagnostic clinics, eye, ear, nose and throat clinics, dental services and x-ray and laboratory services should be had. The organization of a community service department is absolutely essential.

In other words, the hospital's organization should be executive and professional, the latter divided into an intrahospital unit and an extrahospital unit, the latter in charge of a clinical director who has direction of the clinics in the field and of the educational programs and activities, the former under the direction of the assistant medical superintendent.

Such is the ideal background of a hospital in its mental hygiene career. I am not unmindful, however, that there are few if any mental hospitals so well rounded out. On the other hand I feel that it must be a poor institution indeed that does not possess some of these fundamentals. With certain of these fundamentals and the creation of a comprehensive, organized community service department, however, at a little expense such a hospital's efforts would meet with a degree of appreciative response that would tend to lessen the strain and energies put forth to this end.

As I have said, many hospitals, particularly in rural districts, have begun such mental hygiene activities. For the results of such a program, however, I can present only one with authority, and that is the efforts and results of the Danville State Hospital.

In 1920 I made my first contact with this institution. My knowledge of mental hygiene was such as I was able to integrate from the teachings of Mr. Beers himself, Dr. Thomas W. Salmon and Dr. E. Stanley Abbott of the Public Charities Association of Pennsylvania. The institution had an excellent background and physical foundation. It is distinctly rural, serving twelve counties representing an area of 9,170 square miles and a population of 874,000. There were no psychiatrists in the community save those attached to the state hospital and one county institution. No mental clinics were available. (As to the psychiatrist this remains true today excepting for one instance, in one of the cities of our district, and this psychiatrist is associated with us in our clinical work.) There were six educational institutions aside from the public schools. Such was the barren field. Such was the opportunity for service.

The mental hygiene program at that time was sponsoring improvement in our hospitals as related to diagnosis, research and treatment services, also adequate professional services and well trained nurses and physicians and special therapists. In the broader fields were the expansion of social service, the establishment of clinics and the enlightening of the public, the latter rather vague as to how it could best be done. The task confronting the hospital administrator was an organization to meet the needs. An organization with intrahospital and extrahospital functions was the result.

By 1921 the hospital's administrative program was complete, including a community service department embracing mental clinics and educational activities, with a director in charge, Dr. H. V. Pike whom many physi-

cians know and who is associated with me at the present time. Dr. George B. M. Free, assistant medical superintendent, was in charge of the intrahospital activities.

A summary of the results of this service I think, will be sufficient to justify our years of effort in a piece of work, pioneer in nature voluntarily assumed (as it was not a part of the state program) aided only by a sympathetic board of trustees, department of welfare, an appreciative community and a cooperative group of physicians and educators in our district. Furthermore, it represents in a practical way the role of a rural mental hospital in mental hygiene and of one particular pattern now in operation for almost ten years.

Modesty forbids that I stress the virtues of our hospital. However, I must present certain phases of its activities to illustrate certain points. The intrahospital unit is of the modern type. The community service department with an organization consisting of one clinical director and one community service investigator provided by the hospital, with the various cities and towns in the hospital community providing one full time psychiatrist, one part time physician, one part time psychologist, six registered nurses, two social workers and two stenographers, represents the clinical side. The ten mental clinics registered 10,532 visits in eight years. Of these, 4,091 were new cases, 2,587 return visits and 3,854 furlough visits. Of the new patients, 65 per cent were children under 16 years of age and 35 per cent were adults above 16 years of age. These cases were referred by the medical profession, court officials and community agencies. An analysis of these cases in greater particulars was presented to the American Psychiatric Association in 1929. It is interesting to note, however, that of the children examined 83 per cent of these cases are still in the community with only 17 per cent committed to schools and correctional institutions. Of the adults, 73.3 per cent are still in the community with 26.7 per cent having been found to require actual hospitalization. To aid in the supervision, adaptation alone of such a large group in the community represents a saving of thousands of dollars to the commonwealth.

On the side of educational contacts, more than 65,000 teachers and students have been reached with lectures and addresses on mental hygiene. The mental health bulletin published by the hospital has reached central commissions of forty-eight states, also the colleges, schools, libraries and selected readers in our hospital district. Monthly mental health talks have been presented to twelve papers for the past two years serving a population of more than a million readers. About 400 or 500 reprints of these talks are given to visitors to the hospital. If such aggressive attacks as these against ignorance, superstition, legends and traditions meet with no avail, one might as well give up the ghost.

On the medical side we are in close contact with organized medicine. The Montour County Medical Society meets on alternate months at the hospital. An annual mental hygiene meeting is held at the hospital for the physicians of the twelve counties. (In addition to these visitations, from 2,000 to 3,000 college and high school students visit the hospital for the follow up clinics to their lectures and for visitation of the entire hospital each year.) In addition, forty-eight monographs of the nature of research and practical consideration of mental disorders and their treatment have been released for publication. The superintendent and the clinical director serve as regularly appointed neuro-

DR. ROBERT L. LEBRON

U. S. DEPT. OF HEALTH

32615

psychiatrists to three of the larger general hospitals in the district. Consultation is also provided the other general hospitals on request.

This contact with the general hospital, I believe, makes one of the greatest contributions to the mental hygiene movement as it relates to encouraging the general hospital to serve as an examining station, stations for short periods of observation or real treatment agencies for certain recoverable types. The relation to these hospitals I believe has overcome somewhat that old reluctance to receive into a general hospital any kind of patient to whom psychic reactions dominate the clinical picture. Correspondingly, the members of the staff of one institution (the Geisinger Memorial Hospital) serve as consultants to our hospital in their respective specialties: surgery, medicine, roentgen ray, eye, ear, nose and throat. They also receive and surgically treat in their wards mental cases susceptible of hospital adaptation. It has been years since we have had to resort to our own operating room for major operations. We also provide a lecturer on neuropsychiatry for the training schools of these general hospitals.

In the foregoing, I have tried to present in the time allotted me such citations of facts as to warrant the following conclusions:

- 1 The mental hospital can be made one of the keystones of the mental hygiene movement.
- 2 It has and always will play a definite role in research and treatment.
- 3 Its clinics and educational activities are two of the greatest forces in carrying the doctrine of prevention.
- 4 It lends its broad arms to medical education.
- 5 It is one of the greatest mediums for public enlightenment.
- 6 All of which may be done with satisfaction, peace and harmony in its many related fields.
- 7 The cooperation of the physicians in the district will simplify and make possible the approach to the problems.

THE HOSPITAL, THE MEDICAL COLLEGE AND THE INTERN*

A C BACHMEYER, M.D.
CINCINNATI

There is general recognition of the fact that the period which the medical graduate devotes to internship is one of the most valuable in his whole career. The medical college, the hospital and the intern are all vitally interested in the subject.

The medical college has as its most important function the preparation of young men and women for the general practice of medicine. It takes the student after several years of college preparation consisting largely of elementary training in the sciences, and endeavors to give him as thorough instruction as the time will permit in those fundamental sciences that underlie the practice of the profession. They further endeavor to give him an introduction to the theory and practice of clinical medicine. After at least six years of instruction the student comes to the end of his college course. His career thus far has not only been a succession of courses of instruction but a discipline that seeks to form helpful habits of study and self-control that will fit him for his future life. The college

has endeavored to furnish him with all the working tools necessary for his future service, by means of which he may attain proficiency in the practice of his profession.

During at least the last two years of his college course he is daily in contact with patients in the dispensary and wards of the hospital that serves the college as practice laboratory. These contacts have been primarily as auditor, observer and clerk. While he has been held responsible for some of the minor routine duties connected with the care of the patient, his responsibilities have been very limited. He has learned methods of physical examination and diagnostic procedure, he has been guided in making diagnoses and in suggesting therapeutic measures. His instructors have always been at hand and the welfare of the patient has in no wise depended on his decisions or opinions. His work has been constantly scrutinized, verified or corrected, and his graduation is an indication that the faculty of the college believes that he has sufficient knowledge, judgment and ability to begin the practice of his profession.

It has also been the endeavor of the college faculty to imbue the student with the high ideals, ambitions and ethics of the medical profession.

It is generally recognized, however, that even though the clinical training in colleges has been greatly extended and improved in recent years, the student at the completion of his courses is not fully or properly qualified to undertake the responsibilities incident to independent practice.

Fourteen states and as many medical colleges now insist that the graduate spend at least one additional year in supervised clinical work before a license to practice is granted or, in the case of the colleges, the final degree is conferred. The colleges that have imposed this requirement subscribe to the opinion that it is the responsibility of the college to certify to the competence of its graduates to practice medicine. For the most part, those which do not prescribe a fifth year requirement believe that it is the state's responsibility to determine the graduate's fitness to care for the sick or injured.

Those colleges requiring a fifth year of clinical medicine are naturally most interested in the composition of the internship which their students shall serve. They are insistent that it shall provide educational opportunities which are of real value to the student, opportunities for the student to assume responsibility for the care of patients whereby he may enhance both knowledge and experience. It is desired that there be adequate facilities for the modern practice of medicine, for reading and for study. The college expects that the staff of the hospital shall have an active interest in medical education, shall properly supervise the intern's work and shall direct his studies and professional activities. Some individual member of the staff should serve as the intern's preceptor and at the same time as the college's representative. Reports to the college concerning the intern's work should be made. It is only in this way that the college can develop a mechanism that will enable it to maintain proper control of the student during this year and permit it to give academic credit for his work.

Shortly after entering on his clinical studies the student begins to consider the question, "Where shall I serve my internship?" By the end of his junior year he is seriously engaged in an inquiry concerning the subject. He turns quite naturally for advice to the

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 17, 1931.

interns and residents with whom he comes in daily contact. He may consult members of his faculty and also refer to the literature. In many colleges, including the University of Cincinnati College of Medicine, the question of internship is the subject of a formal lecture to the students early in the senior year. The limited time permits only a brief discussion of the situation. The requirements of the college, the organization of the hospital, the importance of its primary function, the place of the intern in its organization, the need for the observance of its rules and regulations, and the necessity for exercising discretion, good judgment and self-control are emphasized. Lists of hospitals approved for internship by the American Medical Association and of those in which former interns have had service satisfactory to the college are published. In addition there are personal interviews between the dean and other members of the faculty and the individual students.

From these interviews, the dean or a selected member of the faculty may obtain an intimate insight into the student's plans and ambitions and be enabled to offer helpful advice or often to direct the student to the type of internship best suited to his needs and instruct him how to proceed in order that his plans may be best accomplished.

Before the University of Cincinnati adopted the fifth year requirement, all its students, for many years, had voluntarily served internships of at least one year's duration. In recent years, however, and I believe this to be true in other colleges as well, an increasing number have planned to spend one or more additional years in clinical training. This desire is often developed in the course of the personal interview, and plans are formulated whereby such extended service may be obtained. Internships are therefore in demand in those institutions in which the opportunities for advanced training are best developed.

In considering the intern, it may be well to picture the young man on the eve of graduation. He is a mature individual who has spent at least six years of his life in college preparing for his life's work. He has acquired a broad training in the fundamental sciences and has had limited clinical experience as a student. He has been imbued with the high ideals of his profession and is enthusiastic and ambitious to put his knowledge into practice. His graduation and the license to practice which he may have acquired by state examination have definitely made him a member of the profession. Before the law he stands as an equal with his seniors, and now, though they may still be his instructors, he is their colleague and he expects to be treated as such. His enthusiasm may lead him into error, but his motives are usually good and his intentions of the best. He is still young enough to enjoy the various sports and needs a goodly amount of physical recreation. He is ready and anxious to go to work. Though he has studied in the wards of a hospital he has not been a part of its organization and has probably not given much thought to the hospital beyond the actual ward performance as he has seen it. He knows little concerning its complexities and is confused by the many rules and regulations he encounters.

The primary object of the internship, as has been indicated, is to provide opportunities whereby recent graduates may obtain practical experience in the practice of medicine under proper supervision. The hospital offering intern training must recognize its responsibilities to the student. These responsibilities

primarily concern the administrator and the medical staff. Their attitude toward the young graduate is of great importance, unless it comprises a recognition of his needs, of the reasons for his service and an understanding of the value of the internship in relation to his future career, unless they provide ample opportunities for experience and study and constantly stimulate in him a desire to make the most of those opportunities they have no right to ask the young graduate to serve in their institution merely in order that tiresome routine duties may be performed.

The administrator and the medical staff together should definitely organize the intern service and see to it that the new intern is properly introduced to the service.

It is the responsibility of the administrator to explain the general organization of his institution. A tour through the hospital before the intern enters on his service with introductions to the several heads of departments, has been found to be very helpful. It is the duty of the administrator to see to it that the hospital provides proper living quarters for the intern staff and that their food and other requirements are adequately served. Recreational facilities should be provided, for it must not be forgotten that these young men and women have need of diversion and healthful exercise.

It is the responsibility of the medical staff to provide for the professional training. The service should be definitely organized and should provide for the assumption of increasing responsibilities by the intern as his ability and proficiency develop. The intern should be placed in direct charge of every patient admitted to the institution, whether indigent and in the free service or a private patient. He should be required to take histories, make physical examinations and diagnoses and direct therapy for all patients under the supervision of the staff. The attitude held toward him by the members of the staff should be that of colleague and consultant. They should thoroughly discuss all elements of the case with him, correct and direct him, and suggest diagnostic and therapeutic measures when necessary.

As a student, the intern has been primarily trained in the scientific, empiric and theoretical aspects of medicine, he should now be introduced more thoroughly into the art of applying this knowledge. He should therefore be taught the proper approach to the patient and to relatives and friends. He should be required to meet those interested in the patient and interpret the observations and opinions of his staff officers, explain to them the progress of the case, the measures of relief and therapy that have been advised, and in every way conduct the case as though he were directly responsible. It goes without saying however, that in all of this he should be guided by his staff and that he should bear in mind the relation of his superior to the patient. Should the patient's malady terminate in death, it should be his duty to make the request for autopsy. In this he can hope to be successful only if he has won the confidence of the relatives.

The medical staff is also responsible for the provision of adequate library facilities. It is its further duty to stimulate the intern's reading and study. By encouraging and insisting on his participation in clinical conferences and in the presentation of theses and case reports much can be accomplished.

In addition to these measures of professional training the staff carries the grave responsibility of the intern's

training in medical ethics. Though he will have had instruction while in college in the ideals and ethics of the profession, the attitude and conduct of the various members of the hospital staff toward one another will primarily influence his future development in this regard. Destructive criticism and questionable practices on the part of intern's staff officers have only too often wrought serious harm to the character and career of a young man. Though the college may have done its task as carefully and thoroughly as possible, the influence exerted by the intern's superiors will take precedence in most cases. It is the hospital, therefore, and particularly the members of the hospital staff to whom we must look for the final development and proper introduction of the young man to the art and ethics of the practice of medicine.

In return for these many educational advantages and opportunities, the hospital has a right to expect that the intern will conscientiously devote himself to his duties, even to those that are uninteresting or of a routine nature, that he will conduct himself as a gentleman and as a full-fledged physician, that he will fit into his important but relatively minor place in the hospital organization in a harmonious manner, do everything in his power for the good of the patients assigned to him and refrain from doing anything that will in any way interfere with the best interests of the patient or of the hospital.

If the college, the hospital and the intern will develop this attitude toward the subject of intern service, a solution of the many vexing difficulties of which each of them often complains can be hoped for and every internship can be expected to be of real educational value.

Cincinnati General Hospital

THE HOSPITAL TRAINING OF INTERNS*

HAROLD L. FOSS, M.D.

Surgeon in Chief, George J. Geisinger Memorial Hospital

DANVILLE, PA.

The present medical school enrolment in the United States (1930) is the largest in twenty years, totaling 21,597 students. There are eighty-seven approved medical colleges in the United States, Philippine Islands and Canada, eleven requiring that students shall have completed a fifth year as intern in an approved hospital before the degree of Doctor of Medicine will be granted, while sixteen states including the Territory of Alaska and the District of Columbia require an internship before the license may be applied for. In 1930 4,561 students graduated in medicine, 119 more than in 1929.

There are at present in this country 648 hospitals approved for intern training, with a total of 193,557 beds furnishing service for 5,496 interns. These internships, which become available and are filled each July, have all been carefully supervised by the Council on Medical Education and Hospitals of the American Medical Association. Many of the services are excellent, furnishing the recent graduate extraordinary opportunities to study disease at first hand and under the direction of splendid teachers of national reputation and of the widest experience. They constitute, however,

but a small percentage of them all, many new doctors being obliged to secure what experience they can in hospitals, the service of which is characterized chiefly by its mediocrity.

DEFICIENCIES OF INTERN TRAINING

In such hospitals there are many basic deficiencies. The men are not taught; there are few discussions of case histories, there is little or no check of preoperative and postoperative diagnosis, there is too much technical training in the laboratory and not enough study of tissue, both gross and microscopic, the intern is given responsibilities for which he is not trained, he is told something of disease but little of its mode of onset, cesarean section is made impressive and dramatic, but nothing is said about pinworms, the intern's studies of the patient are ignored and his tentative diagnosis disregarded although he may frequently be right, the intern is given insufficient opportunity to do things *under supervision*, he is not instructed in making pelvic examinations, there are too infrequent presentations of case reports and other short papers by members of the intern staff with constructive criticisms and analyses by the chiefs. The men are not encouraged in collateral reading, in the study of bibliographies and in preparation of abstracts; they are left too much to shift for themselves; staff meetings are irregularly and too infrequently held, there is too little bedside differential diagnosis, too little training in tact and in the handling of patients and patients' relatives, too few independent diagnoses by the interns adequately checked by chiefs, too few examinations in the nose and throat departments, too little obstetrics, too great a lack of detailed bedside instruction, too few seminars by the staff members for the benefit of the interns, too little explanation by chiefs of the rationale of their treatment.

ESSENTIALS OF A GOOD SERVICE

It is greatly to the intern's advantage to serve a rotating service in a hospital having active services in the various major branches of medicine and with a fairly rapid turnover of patients. Many hospitals curtail the service so far as the examination of the private patients are concerned, a condition I believe to be wrong. The recent graduate in this day is capable, in most instances, of being given carte blanche in the taking of histories and in the making of physical examinations of all the newly admitted patients, not only in the ward but in the private service as well, for it is a mistake to limit these young men merely to the study of the dispensary and the ward case on the assumption that they have not as yet acquired sufficient tact and refinement to render them worthy of the confidence of the patient of the upper walks of life. One of the essentials of their training is the art of handling people, and the opportunity of acquiring and developing it should be fully afforded the intern and he can profit much in this regard from close association with his chiefs. He may thus learn that often men get along more because of tact than of talents.

There is nothing more helpful to the alert intern than well arranged clinicopathologic conferences. They should be held at least weekly, under the direction of the hospital pathologist and his associates. At such meetings a lantern slide giving a brief abstract of the patient's history should be thrown on the screen to be discussed and elaborated on by the men who have had the patient under observation. The pathologist continues

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 17, 1931.

with a discussion of the gross pathologic observations at operation or autopsy, demonstrating the specimens, previously prepared in Kaiserling's or Lundquist's solution and painted with gelatin to render them odorless and dry, supplementing his description of the gross specimen with a demonstration by means of the projecting microscope of the pathologic changes. Any hospital worthy of giving the intern year should have a competent pathologist interested in teaching and willing and able to conduct these most stimulating and helpful conferences.

CONFERENCES AND SEMINARS

In the survey of hospital intern service for 1930 by the Council on Medical Education and Hospitals, 1,491 replies were received from a questionnaire sent to interns representing 700 hospitals. Of the 1,491, all but 84 attended staff conferences but only half attended clinical lectures, and the comment is made that "clinical conferences and lectures, although of unlimited value to the intern, apparently are not being utilized." More than 600 failed to answer the question or definitely reported nonattendance at such meetings, indicating, apparently, that they were not provided.

All well conducted hospitals hold periodic staff meetings, which should always be open to the interns. Such meetings are held monthly in most hospitals, although in the full time staff institutions a weekly meeting is conducted in which the interns take an active part. At these meetings interns should read at least one paper each year, usually based on a clinical study of a large series of cases taken from the hospital records, with a review of the literature bearing on the subject under consideration, the papers to be discussed and criticized by the men of the staff. But this is not enough, besides the regular staff meetings and the clinicopathologic conferences a series of seminars, arranged especially in the interest of the intern and dealing with all the major specialties, should be conducted by the members of the permanent staff. The roentgenologist should have periodic meetings in his department during which films are examined and roentgen diagnosis and differential diagnosis thoroughly discussed. All this may seem somewhat utopian but may be easily arranged and is no more than the conscientious staff should feel it owes the younger men. Such a program is carried out in the institution with which I am connected, a 185 bed general hospital with a full time staff providing service for seven interns and two residents.

TRAINING THE SURGEON

No intern should ever expect to become a surgeon merely on the training secured during a one year's rotating service. I thoroughly agree with the opinion of the Council when it says in its 1930 report that "the idea apparently growing that interns are in hospitals primarily to acquire surgical technic and become surgeons without additional graduate preparation in that subject should be discouraged." Many men limit themselves to a one year's hospital residency before attempting a surgical practice, feeling that they receive thereby sufficient training in this brief space to warrant their entering on the specialty of general operative surgery. That such a thing is being too greatly encouraged in many hospitals has been the finding of the Council. In its last survey it was found that 53 per cent of the interns were permitted to do major surgery. Indeed, some of the operations described would seem to require more mature skill, even if this was performed in most

instances under strict supervision. That a majority of the interns reporting indicated that they are allowed to perform major surgery, even under supervision, at first glance is surprising, if not alarming." Such gross disregard of the welfare of the patient as well as of the good name of surgery cannot be too severely condemned.

A working knowledge of technical surgery is a difficult thing to acquire, requiring much time and patience and far more experience than can be obtained in the few months' surgical service of a one or even two years' rotating service and, by the same token and what is even more important, surgical judgment is acquired only after years of experience. One cannot train surgeons as one used to train children to swim, by throwing them into the water, but that such methods are being all too extensively utilized is manifested daily by the enormous number of unnecessary operations, usually badly done, and on the most meager provocations or on no provocations at all, being performed throughout the country largely by young men who have set themselves up as general surgeons after the most superficial and incomplete hospital training. A serious responsibility rests on any hospital whose organization is so loosely supervised that its interns are encouraged to delude themselves into believing that they may become competent surgeons after such brief and sketchy operating experience.

The young men planning to go into surgery or any major specialty for that matter, requiring a high degree of technical training and manual skill, should consider the one or even two years' rotating service purely as an important and essential period of preparation before obtaining further and more intensive experience in an institution dealing chiefly with that branch of medicine in which he is especially interested and to which he plans devoting his life. In the past fifteen years 64 per cent of our own ex-interns have gone further and taken from one to three years more of graduate study in well known clinics and hospitals. This has been an excellent trend, and it must be encouraged and furthered in all hospitals, especially in those with one year services, if high class, well rounded out men are to be turned out whose training to cope with the complexities of modern diagnosis and therapeutics may be considered at all adequate.

THE LIBRARY

Every hospital having an intern service should possess a well stocked working library. In addition, it should subscribe to the best and more important American medical journals. Our 185 bed institution annually pays the subscriptions for forty-two journals. The books of the library with the current periodicals should be available at all times to the members of the intern staff, while a comfortable and quiet reading room adjacent to the library should be provided. The *Quarterly Cumulative Index Medicus* should have a prominent place, and its use should be explained and the men encouraged in frequently resorting to it.

It is gratifying to note that most interns are receiving ample laboratory instruction yet the comment is made by the Council that it is less gratifying to note that there were 333 of the 1,400 answering questionnaires who did not obtain experience in the laboratory department while only 377 of the 1,491 were receiving x-ray instructions as part of their regular service. Such disregard of their obligations to the intern should render these institutions ineligible to give the intern year and

they should invariably be removed from the accredited list until their deficiencies have been fully corrected

PERSONAL EXPERIENCES

During the past fifteen years I have had sixty interns under my direction in a hospital in which the men spend one year on a rotating service. To these men now in practice for from one to fourteen years, I recently sent a questionnaire dealing with their former intern experiences. All replied, answering certain basic questions and, as was requested, commenting frankly and freely on their intern year now observed from a distance and with the perspective of the experienced practitioner. At the same time our present interns, nine in number, now on active service in the same institution, were asked to prepare a short essay on the subject of the training of the hospital intern as they were observing and experiencing it. They were asked to discuss freely its deficiencies as well as its advantages and to offer frankly any suggestions for the improvement of the service. The information so received has been most interesting and helpful and has really served as a text for this paper.

A request that he speak his mind will never be passed up by the modern hospital resident. He welcomes the opportunity, seizing on it with the greatest enthusiasm as a welcome chance to unburden his mind of matters that have long obtruded themselves and to tell the hospital, the superintendent and all his chiefs just what is wrong with things and how best to correct them. No hospital official should make the mistake of disregarding these expressions from the heart, for they are invariably sincere and are often revealing and invariably are helpful to all concerned. As members of the staff we always know exactly what we think of the interns and they are usually fully appraised in the first few weeks of their service when we estimate and cross index and catalogue them in our minds quite definitely, but rarely do we know what they think of us. If interns were asked to set down with perfect frankness in account, as they see it, of the service given them and of their unalloyed opinion of the men who are responsible for these services, it might be surprising, at least the point of view of the intern and often a lot besides would be learned, most of which would do far more good than any possible harm, unless it be to one's exaggerated and, perhaps, unjustified pride, and this harm, paradoxically, really would do good. Although we have never, in fifteen years of our hospital history made such a survey before, it will hereafter be an annual event, much, we feel, to the future good of the intern service and to a distinct betterment of the relationship between these young men and their chiefs.

THE FULL TIME STAFF AND THE INTERN

There are but relatively few hospitals with full time staffs. The Mayo Clinic, the Henry Ford Hospital, the Cleveland Clinic, the Robert Packer Hospital and the George F. Geisinger Memorial in Pennsylvania are examples. An intern service in an institution so organized offers distinct and unique advantages. The men are constantly under supervision and direction and yet, while given a free hand in the examination and treatment of their patients, are in position to obtain counsel and advice quickly or to be checked and properly directed as the case may require. They are closely associated with men highly trained in their respective fields, all working in the closest harmony in a perfectly coordinated group endeavoring, through the utilization of every means necessary, to make as accurate and as

complete a diagnosis as is possible and with the minimum of delay to the patient, to be followed by the carrying out of the most appropriate treatment. In all this the intern has an active part, passing from one service to another yet constantly in touch with all the services through the medium of frequent consultations, clinicopathologic conferences and staff meetings. In a year's experience on a rotating service such as I have described, with a large and active service rich in varied clinical material, the alert intern should obtain a comprehensive and fairly accurate conception of the entire field of medicine and should be especially well prepared to decide on the branch in which he desires to major and to select the institution in which he can secure intensive training with the greatest advantage to himself.

FURTHER GRADUATE STUDY

Many men are satisfied with a one year's service while others would like to spend more time in institutional work but are obliged, because of economic or other reasons, to forego it. Although not always the best men yet as a rule they are from this group, a larger number each year of our own interns are electing to continue their graduate studies in other hospitals or in investigative work in our great laboratories of research, or to enter on fellowships in one of the several institutions offering such advanced training for the occasional and especially outstanding man. The men of the latter group probably do not constitute more than 5 per cent of all recent hospital graduates, yet from them are coming many of the future leaders.

Referring to my questionnaire, I find that of our recent interns 62 per cent elected to go further with from one to three years more in laboratory or hospital work before going into practice. We have strongly encouraged the continuation of graduate study and, as time goes on, a larger number are failing to rest content with a one year's service. All of our men from the 1929-1930 group continued in hospital work. It is also customary with us, as with many hospitals, to select each year several of the outstanding men, providing them with a stipend of from \$100 to \$150 a month and with hospital maintenance for a year's residency in our own hospital in various departments. We have also sent men of especial capabilities to other clinics for from six months to a year, paying them a living stipend and having them return, ultimately, to take assistantships on the permanent staff. Thus it is possible gradually to build up a staff of especially selected men, all of whom must first measure up to exceptionally high standards of character and natural, inherent ability, one of the greatest advantages of the full time staff plan of hospital organization.

SUMMARY

Irrespective of how well organized the intern service may be and of how great the effort put forth by the heads of departments to render the training of the most practical value, the greatest accomplishment will not be achieved without a certain basic principle being borne in mind. The young doctor fresh from the medical school and entering his intern service begins now to practice more of the science than of the art of medicine. He is in the most formative period of his existence, keen to learn, wide-eyed and enthusiastic, trusting and hopeful, relying tremendously on the guidance of his chiefs, so much so that it places a great responsibility on them the significance of which, I fear, none too frequently bear in mind. "The student acquires a

sense for scientific work only in his student days, and the degree of scientific training and interest imparted to the young man in the medical school (*and hospital*) determines his intellectual level for the rest of his life"¹ And so we should fully appreciate our obligations as teachers, realizing that our role is hardly second in importance to that of the men who have guided the student during his college years and that it is our privilege perhaps more than it was theirs, by our precept and example, by our opportunity to stimulate his latent enthusiasm, by the inspiration of our own personalities to afford him in the most important phase of his professional career that guidance so important in molding and shaping and directing his destinies to the end that his life becomes a failure or a success largely as we choose to make it

THE INDISPENSABLE USES OF NARCOTICS

IN OBSTETRICS AND GYNECOLOGY*

JOSEPH B. DELEE, M.D.
CHICAGO

From time immemorial narcotics have been used to assuage the pains of childbirth, and in more recent times they have been exhibited for sundry complications of pregnancy and the puerperium. Human beings have attempted to lift the curse placed on Eve at the so-called beginning of the human race, ever since that time, and it is not necessary to cast doubt on the authenticity of the story to justify the present use of narcotics in obstetrics.

NARCOTICS IN OBSTETRICS

Sedatives are used during pregnancy, labor and the puerperium. During pregnancy the most common indication for narcotic medicines is the prevention of abortion. Rest in bed, combined with morphine or other preparations of opium, has saved numerous pregnancies from disaster. A combination of chloral with bromides has been used, but it is not nearly as effective. When an acute abdominal condition develops during gestation, or an operation is performed at this time, narcotics are particularly indispensable, to allay uterine action which might expel the ovum.

In the treatment of hyperemesis gravidarum, morphine is occasionally used to stop vomiting for a brief period, in order to allow the intake of food. Tincture of opium is often added to nutrient enemata to allay rectal spasm and aid retention. Cocaine is still used to allay vomiting and permit feeding.

Certain cases of chorea gravidarum do not respond to the usual remedies, and a combination of morphine and scopolamine may have to be exhibited for temporary sedation. The same may be said of the psychoses.

¹ Dean Lewis

These articles are prepared under a plan of cooperation between the American Medical Association, the Committee on Drug Addiction and the Division of Medical Sciences of the National Research Council, and the Division of Mental Hygiene of the United States Public Health Service. Their object is to reduce the legitimate use of addiction drugs to a minimum by replacement wherever possible with other remedies that will accomplish the desired result. The physicians of the United States are the essential group in any such attempt and it is hoped that these articles will be useful to them in their practice. The funds for this work have been donated to the National Research Council by the Bureau of Social Hygiene, Inc.

Pregnancy does not contraindicate the exhibition of narcotics for any purpose that demands them. The child does not suffer except from an overdose that would endanger the mother. Cases are on record in which, it is said, the excessive unwarranted use of morphine during pregnancy has shown effects on the child, but they are too rare for serious consideration. Chloral and chloroform pass over to the fetus but their action need not be considered as important during pregnancy. The barbituric acid preparations have widespread application in obstetrics and thus far no one has shown any bad results in doses safe for the mother, although they rarely procure enough sedative effect.

During labor, opium preparations cannot be dispensed with. Chloral, barbituric acid compounds and other substitutes do not meet the needs of the parturient woman. Our recent experience with sodium amytal in painful labor has been disappointing, and several babies were born narcotized. The pain element varies much in individuals, indeed, not a few labors particularly in multiparous women, may be conducted with only obstetric inhalation analgesia in the second stage.

There is no question in the minds of experienced observers that the routine administration of narcotics in labor, as demanded by hysterical magazine writers and as practiced by many overenthusiastic accoucheurs, has resulted in and is yet causing numerous deaths of newborn children and also a certain number of maternal deaths. On the other hand there is a real and scientifically proved ground for the scientific administration of narcotics during labor. The process of human childbirth is commonly pronounced to be a natural harmless function, but accoucheurs know that, while this may have been the original intention of nature, the modern woman can seldom be brought through the ordeal without some physical damage to her body, that often she cannot be got through alive, and that frequently the shock to her nervous system leaves permanent injury. The pains of labor may be natural but are they physiologic? Are they harmless? Everywhere else in the human organism, pain is a symptom of disease. At any rate, the modern woman cannot stand pain. It leaves its mark, and therefore it is the bounden duty of the obstetrician to reduce the suffering as much as possible within the limits of safety of mother and child.

Also the child is to be considered. The uterine contractions exert a pressure on it that not seldom reaches 45 pounds to the square inch. Its bones have been broken and even its head crushed in by the action of the uterus alone. Compression of the placenta resulting in asphyxia in utero is a minor effect though sometimes fatal. Narcotics, by moderating the force of the contractions and calming their tumult, may relieve the baby from injurious pressure and preserve its life and integrity.

Labor is often protracted, especially in primiparas, and exhaustion of the mother may delay the process so long that infection may creep in. Here a hot pack, and a rectal infusion of chloral with a hypodermic of some opium preparation, will rest the uterus as well as the nervous system, and preserve the heart and the life forces of the patient. When she awakes, the activity of the uterus is resumed with new energy and I have often observed that a stubborn cervix ("rigid os") has become supple and dilatable in the meantime.

The mind of the parturient requires treatment during labor, indeed under few other conditions is the patient more susceptible to suggestion. A sympathetic accou-

cheur with "an understanding heart" may often do more with mental suggestion than can be done with drugs, and he always can increase the potency of his prescription if he adds suggestive influence to the drugs he administers. Sometimes he may exert an almost hypnotic influence on the woman and abolish the memory of pain entirely or nearly so. These cases are of course the exceptions.

Only in the rarest cases is the pain of the second stage bearable by a courageous woman, and in the first stage narcotics are needed as a rule. It is not possible to abolish all pain, but one can and should mitigate it.

Narcotics are said to lengthen the first stage of labor and to affect the child adversely if given in the second stage. Both statements are true, but only when the drugs are improperly administered. Given at the right time and in proper dosage, the child is not endangered and the mother is made more resistant to exhaustion, acidosis, shock and postpartum hemorrhage. By preserving her strength in a prolonged first stage, narcotics actually shorten the second and forestall difficulties in the third. Even the puerperium is more smooth and convalescence more rapid and infection less likely, since the woman's immunities have been preserved.

There are few occasions for the use of narcotics in the lying-in period. After-pains are almost never so severe as to require them, the barbituric acid preparations sufficing to procure sufficient relief. A combination of codeine and acetylsalicylic acid is rarely found necessary. Naturally, any complication of the puerperium that would require narcotics for its own sake must be so treated at this time. Ordinary cases of wakefulness are well handled with a barbiturate. In the sleeplessness that is an obstinate condition in cases of puerperal infection there is no drug as efficacious as morphine, and in the diarrheas of sepsis it must also be used. To rest the bowels in cases of peritonitis I give it occasionally, it affords the patient much relief.

SPECIAL INDICATIONS FOR NARCOTICS

Eclampsia—Morphine is the obstetrician's sheet anchor in this disease. Sodium amytal, magnesium sulphate, chloral and bromides may occasionally be used either alone or as adjuvants, but morphine can best be relied on to make an impression on the frequency or the severity of the convulsions. It saves many lives.

Placenta Praevia—Occasionally the uterine contractions of labor with placenta praevia are strong and separate the placenta, causing free bleeding. While preparations for definitive hemostasis are being made, a hypodermic of morphine will calm the uterus, reduce the bleeding and soothe the patient, allaying her apprehensions and removing the fear of impending death. The same may be said, but with greater emphasis, in cases of abruptio placentae.

As an Aid to General Anesthesia—A narcotic may sometimes replace a general anesthetic. Many minor obstetric operations can be done under morphine and scopolamine, or morphine, scopolamine and a little local anesthesia with procaine hydrochloride. Cesarean sections and even Porro cesarean operations are done under local anesthesia supplemented by morphine and scopolamine. A dose of morphine will reduce the amount of ether necessary for an operation and will thus eliminate such hazards as nephritis and pneumonia.

Postpartum Hemorrhage—For the restlessness and exhaustion attendant on a severe postpartum bleeding, or bleeding from any cause, morphine is the sovereign

remedy, and for shock, following difficult, forceful obstetric deliveries it likewise is most useful.

In cases of incarceration of the placenta post partum, morphine is given for its paralyzant effect on the uterine spasm. After this subsides, the normal uterine contractions expel the placenta into the vagina, from which it can be safely removed.

NARCOTICS IN GYNECOLOGY

In general, what is said of the use of morphine and its derivatives in surgery applies equally well to the practice of gynecology.

Cocaine is not used much in obstetrics or gynecology, but procaine hydrochloride has extensive employment in both specialties. Morphine as a general sedative in gynecologic operations done under local or spinal anesthesia may be given much more extensively and in larger doses than in obstetrics, as there is no baby to be looked after.

At the present time various barbituric acid preparations, tribrom-ethanol and other drugs are being used to supplant morphine as the preliminary hypnotic before operations with a general anesthetic, but their success is somewhat dubious and there will always be cases that will not respond to them at all. Here, however, much progress is being made. Care is to be observed, as deaths have already been reported from tribrom-ethanol and barbituric compounds.

Most gynecologic operations can be done under local anesthesia with morphine, or under spinal anesthesia with or without morphine, and when a general anesthetic is given the morphine reduces the amount needful and obviates to an appreciable extent the incidence of post-operative complications affecting the lungs, the kidneys and the nerves. Perhaps the newer hypnotics can supplant morphine here.

For the postoperative pain and abdominal symptoms morphine is indispensable, and the narcotic often saves life by its sedative influence on the bowel. In a few milder conditions the hypnotic drugs may suffice. To bind up the bowels following plastic operations in the pelvis, opium preparations are necessary.

In the treatment of chronic gynecologic diseases morphine has only limited uses, in fact, had better be dispensed with if possible. The severe hemorrhages from fibroids and carcinoma require other management; only the acute anemia may need to be combated by narcotics. There is, however, one grand exception to the hesitancy with which narcotics are given to gynecologic patients—that is, cancer. For the woman suffering the pains of incurable cancer, morphine is the great savior, it should be given often and in sufficient dosage.

426 East Fifty-first Street

Blood Pressure and Hyperthyroidism—The relationship between blood pressure and hyperthyroidism is significant if some views of the present day are true. It is common knowledge that there is an increased pulse pressure in hyperthyroidism. Statements have been made that, if this were continued over a sufficient time, cardiovascular changes and permanent arterial hypertension might ensue. Furthermore it is the belief of some writers that the nontoxic adenomatous goiter can lead to similar changes over a period of years. There has been no adequate survey as far as I am aware to show that either active hyperthyroidism or prolonged but slight overactivity of the thyroid in otherwise clinically nontoxic goiter leads to permanent cardiovascular degeneration, hypertension or cardiac enlargement.—HURVATH, L. M. Blood Pressure Before and After Operation in Hyperthyroidism. *Arch. Int. Med.* February, 1931.

HOSPITAL SERVICE IN THE UNITED STATES

TENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Although business and industry were slack in 1930, the total work done by all hospitals in the United States for the year showed an increase over the preceding year. But not all hospitals were equally busy. While governmental and other charitable hospitals were burdened with an unusually large number of patients, those that serve pay patients generally suffered a decrease in patronage. The total of patient-days in all the 6,719

Chart 1—Total beds in hospitals (in thousands of beds) White, federal; shaded, state; black, all other

registered hospitals during their last fiscal year, according to reports received in recent months, amounted to 278,634,430 days. The number of patient-days in all registered hospitals for the preceding year, 1929, was 265,269,590. The increase for 1930, therefore, was 13,364,840 patient-days. Every patient in a hospital during the year 1930 had at least the consolation of not being singularly unfortunate, he was simply one of a daily average of 763,382 persons who were occupying beds in hospitals. The daily average number of patients in hospitals in 1929 was 726,766, there was, therefore, a growth in the daily average number of patients of 36,616.

During the year 1930 the number of beds in all types of hospitals rose from 907,133 to 955,869, an increase of 48,736 beds. These figures do not include bassinets. The total bassinets in all types of hospitals in the United States rose during the year 1930 from 47,939 to 49,584, a growth of 1,645 bassinets. Our 1930 census of patients does not include new-born infants, but if each bassinet represented the same number of births as last year, the number of births in hospitals was approximately 644,592.

The best available statistics of hospitals grouped according to ownership or control and according to the type of service rendered are shown by states in tables 1 and 2. Much information also is given in the several charts and smaller tables. For data regarding individual hospitals, the reader is referred to the list on page 1023 of this issue. That list is printed in two sections for each state. The first section is headed "Hospitals and Sanatoriums," and the second "Related Institutions." This classification is explained on page 1022.

PROPORTION OF HOSPITAL BEDS OCCUPIED

It is to be expected that a certain proportion of beds in hospitals will be idle because of irregularity in the prevalence of sickness and injuries, seasonal changes, interference for repairs, and reserves for emergencies. For the year 1930, especially, there was an unusual slump in the patronage of hospitals maintained by non-governmental agencies. Following is a summary of the daily average number of unoccupied beds in the 6,719 registered hospitals for their last fiscal year as compared with the preceding year.

	Unoccupied Beds (Average)	
	1929	1930
(I) According to Ownership or Control		
Federal	13,868	13,082
State	21,664	2,070
County	19,025	13,086
City	14,688	15,184
City county	2,807	2,607
Church	37,783	41,684
Fraternities	1,656	1,827
Industrial	3,107	2,144
Individual or partnership	17,373	18,609
Independent associations	54,794	58,233
Total unoccupied beds all hospitals	180,367	197,487
(II) According to Type of Service		
General	123,023	131,223
Nervous and mental	18,079	27,877
Tuberculosis	10,603	9,468
Maternity	2,022	2,401
Industrial	3,150	3,229
Convalescent and rest	1,886	2,340
Isolation	4,741	5,115
Children's	1,807	1,841
Eye, ear, nose and throat	1,783	1,269
Orthopedic	1,110	1,040
Skin and cancer	78	72
Hospital departments of institutions	9,148	9,477
All other hospitals	1,911	1,631
Total unoccupied beds all hospitals	180,367	197,487

HOSPITALS ACCORDING TO TYPE OF SERVICE

The number of general hospitals far exceeds the number of any other type. There were 4,302 general hospitals in 1930, as compared with 4,268 in the pre-

Chart 2—Percentage of beds occupied in hospitals according to type of service 1930

ceding year. In 1930 the bed capacity in general hospitals increased from 357,034 to 371,609. The increase in the number of patients has been proportionately less than the increase in capacity, since the average number of patients for 1929 was 234,009, whereas in 1930 it

TABLE 2—Number and Capacity of Hospitals According to Type of Service—Continued

[illegible]

was 240,384. Of the beds in general hospitals, 64.7 per cent were occupied on the average in 1930, compared with 65.5 per cent in 1929.

Statistics given in these columns do not include newborn babies except when it is clearly stated that they are included. The number of bassinets in general hospitals increased from 42,715 to 43,941. This gives

Chart 3—Total patient days in hospital according to types of service (in millions of days)

some idea of the importance of the maternity service of general hospitals, which have about nine times as many bassinets as all other types of institutions combined. The relative importance of general hospitals is conceded because of their comprehensive service for the sick and injured in a community and the large part they play in the training of residents, interns, medical students and nurses. Patients suffering from nervous and mental diseases, those having tuberculosis, and other special types of patients, are being cared for in general hospitals to an increasing extent.

HOSPITALS FOR NERVOUS AND MENTAL PATIENTS

Last year it was stated in the Hospital Number of THE JOURNAL, regarding the rate of growth of hospitals for nervous and mental patients, that "if the present

TABLE 3—Hospitals for Nervous and Mental Patients in Continental United States Classified According to Ownership or Control

Classification	No. of Hospitals	Rated Capacity	No. of Patients	In-hospital	Out-hospital	Physical Therapy
Federal	21	17,602	16,634	20	20	19
State	229	362,671	347,635	1,275	175	114
County	58	27,000	24,859	7	9	8
City	9	12,301	11,961	7	2	4
Total governmental	317	419,222	400,390	206	206	141
Church	21	3,935	3,527	7	4	5
Industrial	1	20	20	4	0	1
Individual and partnership	127	4,469	3,061	39	0	42
Independent associations	90	9,885	8,035	79	15	46
Total nongovernmental	244	18,317	14,637	80	26	97
Grand total	561	437,539	415,027	286	232	242

rate continues, and there is no apparent reason for thinking it will not, by 1934 we shall have more than one-half million persons in our nervous and mental institutions." The figures for 1930 compared with those of 1929 bear out the prophecy thus far, showing an increase in the average daily census from 395,407 to 415,042, or a net increase of 19,635. At the same

time the total capacity of these institutions increased from 414,386 to 437,919, a net increase in capacity of 23,533. It is interesting to note that 94.8 per cent of the beds available in these institutions were occupied, as compared with 64.7 per cent of the beds in general hospitals.

Hospitals for nervous and mental patients are as a rule much larger than general hospitals. Indeed, although the total number of nervous and mental hospitals is 561, as compared with 4,302 general hospitals, their total capacity exceeds that of general hospitals by 66,310. The average capacities of the various groups of nervous and mental hospitals are

Federal	838.2 beds
State	1,583.8 beds
County	465.5 beds
City	1,367.0 beds
Nongovernmental	75.1 beds

However, if St. Elizabeths Hospital at Washington, D. C., were not considered, the average capacity of the federal group would drop to 651.3, and, if the Philadelphia hospital were not considered, the average capacity of the city group would be 946.

The importance of the 229 state hospitals in their relation to the entire nervous and mental group is apparent. Their number is 40.8 per cent of the total, and they contain 82.8 per cent of all the beds. The great size of these state institutions is made necessary by the fact that most of their patients remain for years.

TABLE 4—Hospitals for Nervous and Mental Patients Showing Distribution in the Various States According to Ownership or Control

			Total	317	244

In the nongovernmental or privately owned hospitals, on the other hand, patients usually remain for a relatively short time, and for this reason the nongovernment-owned group serves a much larger patient population than this comparison of capacities indicates.

A consideration of nervous and mental hospitals by states reveals the fact that the government-owned and nongovernment-owned have grown up together. In the six states with one government hospital each there are four nongovernment. In the nine states having four government hospitals each, or a total of thirty-six, there are thirty-three of the nongovernment. The three states having seven government hospitals each a total of twenty-one, have thirty nongovernment

The three states with nine government hospitals each, a total of twenty-seven, have twenty-five nongovernment hospitals. The three states with twelve government hospitals each, a total of thirty-six, have twenty-eight nongovernment hospitals. Such comparisons, with others easily made by reference to an accompanying table, make it clear that in every section of the country so densely populated as to have nervous and mental patients in large numbers, governmental and nongovernmental agencies have both been active in the solution of the problem.

EDUCATIONAL FUNCTIONS OF HOSPITALS FOR
NERVOUS AND MENTAL PATIENTS

Of the 561 nervous and mental hospitals, 31 are affiliated with medical schools, for teaching purposes. In addition, the Council on Medical Education and Hospitals lists 63 as offering 302 approved residencies in psychiatry. Twenty-six general hospitals also are

studied in this field. The importance of this matter is increased by the fact that only 17 of the 64 four-year medical schools in the United States require of their students as much as 100 hours of psychiatric study.

The increasing medical interest in this group of institutions, until recently thought of as custodial only, has already resulted in changing to a degree their "atmosphere." Clinical laboratories, x-ray equipment, physical and occupational therapy departments and other diagnostic and therapeutic facilities are being added, thus making these institutions places for reconstruction rather than merely for incarceration. An accompanying table shows the extent to which some of these facilities are now provided.

TUBERCULOSIS HOSPITALS

During 1930, tuberculosis hospitals, in which there has been a slight decrease in bed capacity during recent

Map showing location of hospitals for nervous and mental patients in the United States. Government hospitals are marked by a circle and nongovernment hospitals by a star.

TABLE 5—Percentage of Beds Occupied in Hospitals
According to Types of Service

	1929	1930	Difference in Percentage of Beds Occupied

listed as offering 108 additional approved residencies for the study of this specialty. A wider survey would doubtless reveal a great many other opportunities for

years expanded remarkably, increasing from 61,310 to 65,940. The average number of patients grew from 50,707 for the year 1929, to 56,372 for the year 1930. The proportion of beds occupied in tuberculosis hospitals was 85.5 per cent.

MATERNITY HOSPITALS

Maternity hospitals, used by only one tenth as many maternity patients as general hospitals, increased in number from 146 to 151, in bed capacity from 5,434 to 6,527, and in the average number of patients, not including the babies, from 3,412 to 4,126.

INDUSTRIAL HOSPITALS

Industrial hospitals continued the slight downward trend in bed capacity that has characterized them for the past four years. During 1930 they occupied from 7,004 to 6,875 beds, and from 3,824 to 3,664 in the average census of patients.

CONVALESCENT AND REST

A slight gain took place in the number of institutions for convalescents, from 149 to 162, a rise in bed capacity from 6,474 to 7,374, and an increase in daily average census from 4,588 to 5,034. Their rate of occupancy, amounting to 68.3 per cent of their total capacity, was nearly 4 per cent higher than that of general hospitals.

TABLE 6—Total Patient Days, According to Types of Service

	1927	1929	1930
General hospitals	83,906.60	84,411.98	87,740.160
Nervous and mental	127,028.45	144,323.11	151,410.30
Tuberculosis	18,536.160	18,508.03	20,377.780
Maternity	1,448.67	1,740.380	1,701.990
Emergency (Industrial)	1,314.880	1,311.760	1,700.700
Convalescent and rest	2,030.98	1,674.620	1,837.410
Isolation	1,191.360	917.10	908.50
Children's	1,272.70	1,308.890	1,170.940
Eye, ear, nose and throat	1,482.270	400.00	23.04
Orthopedic	1,626.440	1,740.320	1,754.86
Skin and cancer	223.01	298.110	309.015
Hospital dept. of institutions	4,541.34	6,688.160	6,117.01
All other hospitals	1,657.720	2,234.89	2,550.180
Totals	241,216.680	266,269.590	278,634.430

ISOLATION HOSPITALS

Isolation hospitals, which increased in capacity from 7,422 to 7,608, declined in the total daily average of patients from 2,677 to 2,490. Their rate of occupancy was only 32.7 per cent.

CHILDREN'S HOSPITALS

Reference to the column for children's hospitals in the accompanying table reveals a constancy in the number and bed capacity, but an increase in the daily average census from 3,586 to 3,756.

EYE, EAR, NOSE AND THROAT HOSPITALS

Hospitals devoted to eye, ear, nose and throat, and the orthopedic hospitals, showed a gain in the total capacity and the average number of patients cared for.

SKIN AND CANCER HOSPITALS

While the number of hospitals for malignant diseases, under the title of skin and cancer, decreased slightly, the average census of patients rose from 818 to 1,011.

INSTITUTIONAL HOSPITALS

Hospital departments of institutions, including school infirmaries and prison hospitals for the care of inmates, declined in number from 473 to 460 but increased both in bed capacity and in the number of patients.

HOSPITALS ACCORDING TO OWNERSHIP OR CONTROL

Government-owned hospitals, including federal, state, county, city and city-county institutions, now have a total capacity of 619,726 beds and 6,303 bassinets, as compared with 582,537 beds and 6,062 bassinets one year ago. The daily average of patients in government-owned hospitals increased during the past year from 516,885 to 550,737. Sharing in this enormous expansion in governmental participation, the federal hospitals increased in bed capacity from 59,901 to 63,581, and in average census of patients from 46,033 to 50,499; the state hospitals, from 385,706 to 405,309 in bed capacity and from 364,042 to 380,279 in average number of patients; county hospitals, from 65,619 to 73,615 in bed capacity and from 52,994 to 60,529 in daily census of patients; city hospitals, from 57,128

to 63,064 in bed capacity and from 42,440 to 47,880 patients, while city-county hospitals show a slight decrease from 14,183 to 14,157 in bed capacity but increased from 11,376 to 11,550 patients.

In striking contrast with the foregoing facts, the total figures for all the nongovernmental hospitals, including church, fraternal, industrial, individual and partnership, and independent hospital associations, show only a slight total increase in patronage. Their bed capacity was increased from 324,596 to 336,143, but the increase in patients was only from 209,881 to 212,645; there were, therefore, added 11,547 beds but only 2,764 patients. The church hospitals increased

Chart 4—Total bed capacity of hospitals according to types of service 1930

their bed capacity from 113,555 to 116,846 while they suffered a slight loss in total patronage, their average census being 75,770 for 1929 and 75,162 for 1930.

TABLE 7—Increase in Seven Years According to Ownership or Control

	Hospitals		Bed Capacity		Aver. Patients	
	1923	1930	1923	1930	1923	1930

Grand total all hospitals	6,830	6,719	765,722	955,869	523,133	763,382

Hospitals owned by individuals and partnerships similarly increased in their total capacity from 37,977 to 38,557 beds but fell in average census of patients from 20,604 to 19,948. Fraternal hospitals, as a group, made some growth in capacity and nosed out a slight increase in patronage. That large group of hospitals controlled by independent hospital associations, whether incorporated for profit or not for profit, continued their growth, as a group, from a total of 160,971 to 168,431.

beds and from 106,177 to 110,198 in their average census of patients. Hospitals maintained by industries, mainly for employees, fell off considerably both in capacity and in the average number of patients. The

in the United States has grown from 421,065 beds to 955,869 beds, an increase of 534,804 beds, or 127 per cent, in the twenty-one years. In the same period the total hospitals in the United States increased in number from 4,359 to 6,719. Other notable changes that took place were the growth of federal hospitals from a total

capacity of 8,827 beds in 1909 to 63,581 beds in 1930—an increase of 54,754 beds, or 620.3 per cent. State hospitals increased in number from 232 to 581 and in capacity from 189,049 beds to 405,309 beds, an increase of 216,260 beds, or 114.3 per cent. During this time all other hospitals than state and federal increased from 4,056 to 5,850, and in capacity from 223,189 beds to 486,979 beds, an increase of 263,790 beds, or 118.2 per cent, in capacity.

A reliable inventory, or census of hospital service based on the number of patient-days was not made until 1923. The number of hospital patient-days for that

Totals	70	4,440	2,841	4	601	700	144	1,000

The number of hospitals having physical therapy departments prior to 1927 is not known.

year, by groups and in totals, is given in an accompanying table. The total patient days in all hospitals in 1923 was 201,792,545 and for 1930 it was 278,634,430—a growth of 38.1 per cent in the seven years. During those seven years the growth by patient days in governmental hospitals as a group was 47.1 per cent, as contrasted with a 19.2 per cent growth in the non-governmental group.

COUNTIES HAVING HOSPITALS

The accompanying table of counties having a hospital affords an opportunity to observe the number of counties in each state that had one or more hospitals per cent.

munity use in 1920, as compared with the number of counties having similar hospital service in 1930. This does not refer to county hospitals as such but to any hospitals maintained within those counties by any agency and available for hospitalizing the sick and injured of the community. During the ten year period the total number of counties having hospitals increased from 1,332 to 1,829, a net increase of 497 counties.

In 1920, only 44 per cent of the 3,027 counties then existing in the United States had hospitals. By 1930, 59.5 per cent of the 3,076 existing counties had hospitals.

TABLE 12—Counties Having Hospitals

State	Total Counties		Counties Having Hospitals		Per Cent of Counties Having Hospitals	
	1920	1930	1920	1930	1920	1930

Wyoming	21	24	14	14	66.7	58.3
Totals	3,027	3,076	1,332	1,829	44.0	59.5

Many of the counties that do not have hospitals are quite well served by hospitals in neighboring counties. The way in which hospital service has been made available to all communities by the network of splendid highways built mainly in the last ten years is an item of importance.

It is obvious that the percentage of counties that have hospitals located within them is not the only, and probably not the best, gauge to the adequacy of hospital service for a given state or area. It is, nevertheless, a gauge that can be tabulated and, therefore, easily grasped.

SCHOOLS OF NURSING

In 1923 when the Council made its first complete census of schools of nursing, it found the number of state accredited schools to be 1,586 and of unaccredited

schools 378, a total of 1,964. In 1930 it found 1,764 state accredited schools. The number of unaccredited schools was not obtained in the 1930 census.

The number of schools of nursing in the different years for which those numbers were obtained are as follows:

	State Accredited	Unaccredited
1923	1,586	378
1926	1,814	264
1930	1,764	not known

The lists of hospitals registered by the American Medical Association as printed in this issue of THE JOURNAL point out accredited schools of nursing with a heavy black dot (•), and affiliated schools with a dotted circle (○).

HOSPITALS IN THE UNITED STATES POSSESSIONS

Reports were received from 186 hospitals in the territorial possessions indicating that they have a total capacity of 16,916 beds accommodating an average of 12,036 patients. There was an increase of average number of patients in the Canal Zone, Hawaii, the Philippine Islands and Porto Rico, but returns from all the possessions for the 1930 census are still incomplete. The names of those territories and names of hospitals therein from which reports have been received are included in the list of hospitals in this issue.

TABLE 13—Hospitals in the United States Possessions

Territory	Hospitals	Beds	Basinsets	Average Patients
Alaska	16	446	37	205
Canal Zone	10	1,794	40	1,330
Guam	1	60		90
Hawaii	41	4,565	101	3,414

HOSPITAL INTERNSHIP—THE FIFTH YEAR
IN MEDICINE

The 664 hospitals approved for internship by the Council on Medical Education and Hospitals at the present time afford 5,584 internships. At the same time the total number of medical graduates for the year 1930 was 4,565, making 1,019 approved internships in excess of the total number of available medical graduates. Because of this shortage of 1,019 interns, some hospitals already approved for internships will necessarily be disappointed.

With the more thorough inspection of hospitals during the past two years, fifty-one hospitals have been removed from the list of hospitals approved for internships, but new hospitals approved in the same period more than compensate for that shrinkage. The resulting competition among hospitals for available interns is one of the factors that tend to improve the internship, making it a real fifth year in medicine.

Some of the hospitals that find themselves not suited for the general internship or fifth year in medicine are offering residencies that afford educational opportunities for graduates who already have had their general internship.

In connection with the shortage of interns, hospitals and particularly their medical staffs might well consider ways of making their internships educationally more

attractive through autopsies and other means of teaching interns. The rates of autopsies for the 605 hospitals thus far reporting for the calendar year 1930 are as follows:

Percentage of Autopsies	No. of Hospitals
100-90	0
89-80	4
79-70	10
69-60	26
59-50	26
49-40	59
39-30	87
29-20	184
19-15	143
14-10	45
9-5	18
4-1	2
None	1
Not reporting	59
Total	664

The problem of more and better autopsies should be a matter of continued education. Consideration has been exercised in the administration of the requirement of a 15 per cent autopsy rate.

A canvass of all the hospitals approved for intern training discloses that 20 of the 664 hospitals reported a straight service internship and 644 hospitals a rotating or mixed service, including 12 that have no obstetric service.

The list of hospitals approved for internships is subject to constant revision by periodic inspections and by comprehensive reports furnished by the approved hospitals, regarding their internships.

In the twelfth edition of the American Medical Directory, now being prepared for publication, the hospitals approved for internships will be indicated with a five point star (*). They are marked the same way in the list of hospitals published in this issue. A list, strictly up to date, is available at all times on application to the Council on Medical Education and Hospitals at 535 North Dearborn Street, Chicago.

Copies of the approved list are sent to all the medical colleges with the request that one copy be placed in the library or in the office of the dean, and another one posted on the bulletin board.

The biographic files of the American Medical Association contain the records of all physicians, interns and medical students. The record includes the name of the hospital in which the internship is served, giving the date of beginning and date of the end of the internship. In this way each intern is guaranteed credit for his hospital internship.

In case a contract of internship is broken without a release from the hospital, it is the privilege of both the intern and the hospital to write the Association and tell why the contract was broken. Both letters are kept in the permanent files of the Association together with another one from the dean of the medical college from which the intern graduated.

Graduates, therefore, should exercise great care in selecting an internship and in signing a contract. If for any reason it becomes necessary to terminate such a contract, a mutual understanding should be arranged and a written release obtained from the hospital. It would be well if a copy of that release were filed with the American Medical Association.

THE FUNCTION OF THE HOSPITAL IN GRADUATE MEDICAL EDUCATION

Residencies in Specialties—The means of obtaining graduate medical education in any special field has undergone a great change in the last fifteen or twenty

years. Formerly the prospective specialist was compelled to visit the greater clinics in this country and abroad, observing there the work and methods of those who were masters in their particular fields. After a certain amount of this he perhaps became eligible for an assistantship in one of these great clinics. Many excellent specialists were thus trained.

There is being developed however, a method whereby greater numbers of doctors can avail themselves of graduate opportunities. Two factors have been responsible for this. First, the improvements in medical education which have resulted in the developing of more well qualified teachers and, second, the improvements in hospital service and, more important, in the staffs of the hospitals. It became evident that there were more than two or three great teachers in this country in any one specialty. That such clinical teachers were being developed in the better hospitals was recognized by the Council on Medical Education and Hospitals in 1925 when it published a list of "Hospitals Providing Approved Residencies in Certain Specialties." There were forty-six in the list. In its report to the House of Delegates in 1924 the Council said:

HOSPITALS AS GRADUATE MEDICAL SCHOOLS

There are 285 hospitals in the United States offering advanced internships in the various specialties, many of which might easily be developed into acceptable graduate medical schools. In these or other hospitals scattered throughout the country there are doubtless physicians who, in education and special training are eminently qualified to supervise the instruction of other physicians and who also have access to sufficient clinical material to provide excellent graduate medical instruction. There is a great opportunity, therefore, to enlarge greatly the opportunities for graduate medical education by searching for these teachers and stimulating the development of graduate courses either as independent teaching hospitals or as courses affiliated with or otherwise relating to, graduate schools of medicine.

This list of approved hospitals has grown until at present there are 349, with a capacity of 218,495 beds providing 2,069 residencies. Today the great majority of graduates intending to specialize enter their specialty in these hospitals and are in residence for two, three or more years. No degree is conferred at the end of that time, but at least in those hospitals which have appeared on the list of hospitals approved for residencies by the American Medical Association there is reasonable certainty that these men are receiving the fundamental training which will fit them to grow and develop in their chosen fields.

No discourse on graduate medical education would be complete without mention of the thorough work that is being done at schools such as the University of Pennsylvania, the University of Minnesota and the graduate school now being developed at Columbia University through its merger with the New York Postgraduate Medical School. However relatively few men are privileged to take their work in these institutions. Hence the necessity of developing adequate graduate instruction by means of residencies for those who are to form the great bulk of specialists.

A committee appointed by the Association of American Medical Colleges in October, 1927, defined graduate medical study as follows:

Graduate medical study is special medical education given in decided fields in medicine, surgery, obstetrics, gynecology, pediatrics, dermatology, venereal diseases, otolaryngology, ophthalmology, radiology, pathology, bacteriology, physiology, pharmacology, and the like, and is the basis for the development of the specialist.

ment of the medical school. One academic year devoted to the study of a single (convention) medical subject is the minimal matriculation period and constitutes credit toward a graduate university degree maturing within a minimum of two academic years for a master's degree and within a minimum of three such years for a doctorate degree. The first year provides for appropriate special fundamental studies entirely scientific or partly scientific and partly clinical, and may also include research. The second year provides for advanced special scientific or clinical practice and thesis work. The third year provides for special scientific or clinicoscientific research, but may also include some practical clinical or teaching work. Graduate medical studies are available to graduates in arts or science or medicine. The degrees concerned are (1) Master of Science, (2) Master of Science in Medicine, (3) Doctor of Science in Medicine, (4) Doctor of Philosophy, (5) Doctor of Public Hygiene, (6) Doctor of Public Health. Any of these degrees may be granted to doctors of medicine, but the first and fourth are the only degrees available to other graduate students.

This no doubt represents the ideal training for the clinical specialist but is difficult of emulation in a hospital not connected with a medical school. It is becoming increasingly evident, however, that competent specialists can be developed within a reasonable period of time in a hospital which is fortunate enough to have a few real clinical teachers and sufficient clinical material. In a recent address before the Annual Congress of the Council on Medical Education and Hospitals Dr. Henry A. Christian spoke as follows:

It is by no means necessary that a teaching hospital have any association with a medical school. In fact numerous hospitals affiliated with medical schools are not what I would regard as teaching hospitals. Any hospital may become a teaching hospital when members of the staff follow the general methods applied in graduate instruction in university departments of science, literature, etc. In a teaching hospital there should be a resident staff of several grades: interns or house officers, assistant residents and residents. The resident staff forms the student body with interns as apprentices and assistant residents and residents as graduate students; the latter having considerable free time to carry on investigation.

The teaching hospitals, therefore, through their better trained staffs are affording greater clinical opportunities than ever before for the graduate student. In striving for improvement on the educational side these hospitals will do well to pattern after the ideal attained in the university graduate school.

THE SIZE OF HOSPITALS

Hospitals having over 300 beds do 66.8 per cent of all the hospital work as graded by their total average daily census of patients. By the same measure, 8.3 per

TABLE 14—Number and Capacity of Hospitals According to Size

Size of Hospitals	Number	Per Cent	Capacity		Beds	Average Patients
			Beds	Per Cent		
Over 300 beds	516	7.6	579,801	58.5	6,167	10,742
From 201 to 300 beds	3,22	5.2	87,397	9.1	7,242	62,854
From 101 to 200 beds	830	12.3	110,282	12.4	12,611	82,192
From 51 to 100 beds	1,213	18.6	93,223	9.7	10,019	55,178
From 26 to 50 beds	1,685	23.5	61,011	6.3	7,490	33,042
From 10 to 25 beds	1,930	28.8	33,771	3.4	4,111	16,012
Under 10 beds	245	3.6	1,794	0.1	450	742
Total	6,719		958,661		49,854	763,382

cent is done in those hospitals having between 201 and 300 beds, and 10.8 per cent in those having between 101 and 200 beds.

Hospitals having between 51 and 100 beds have 7.6 per cent of the patients; 26 to 50 beds, 4.3 per cent; 10 to 25 beds, 2.1 per cent; and institutions of less than 10 beds, 0.09 per cent.

OUTPATIENT DEPARTMENTS OF HOSPITALS

A carefully prepared questionnaire was sent to all of the 1,799 hospitals that in 1929 claimed to have outpatient departments. As a result of the questionnaire and a follow-up, 1,178 sent reports complete enough for tabulation. Of the 621 that did not return a report, not a few wrote that they did not have an outpatient department in the sense of an organized, equipped department for the examination and treatment of ambulatory patients.

Reports from a total of 1,178 outpatient departments are very significant in comparison with the 678 that responded to a similar questionnaire in 1922, for the year 1921. The number and classification of outpatient departments reporting in 1930, for the year 1929, were as follows:

General outpatient departments	109
Special outpatient departments	
Tuberculosis	5
Venereal disease	5
Nervous and mental	10
Eye, ear, nose and throat	10
Orthopedic surgery	10
H. Collapsion	10
Total	119
Miscellaneous: cancer, dental, emergency, skin and cancer and physical therapy	

TABLE 15—Outpatient Service by States Comparing 1921 and 1929

Utah	502,682	3	4	4,196	4,899	3,094	7,809
Vermont	339,092	3	3	2,800	1,762	1,570	1,809
Virginia	2,419,471	7	16	14,476	49,383	31,917	169,109
Washington	1,561,967	1	12	6,974	38,200	20,971	97,628
West Virginia	1,728,510	10	10	5,009	16,581	7,739	76,513
Wisconsin	2,990,982	11	12	68,400	40,504	199,401	170,289
Wyoming	224,097	2	3	1,820	1,792	3,990	8,821
Totals	192,698,100	678	1,027	3,000,163	6,644,083	9,527,123	19,066,394

In the 1,027 general outpatient departments, 6,644,983 patients were examined and treated in 1929, and they made a total of 19,056,394 visits, in 1921, in the 678 outpatient departments, 3,000,163 patients were examined and treated, and they made a total of 9,522,123 visits. Such a comparison can be made since the proportion of replies received for 1929 is approxi-

outpatient departments more rapidly than those in other sections of the country, in the last eight years. This is no doubt due to the fact that whereas in the past the majority of outpatient departments were in the larger cities today many of the hospitals being built in the smaller cities contain outpatient departments. Older hospitals have also organized such departments. In

TABLE 16—Increase in Outpatient Service According to State Groups

	Population 1930	Per Cent of Increase Over 1922	General Outpatient Depts		Per Cent of Increase	Number of Patients		Per Cent of Increase	Number of Visits		Per Cent of Increase
			1921	1929		1921	1929		1921	1929

South Atlantic states Del. D. C. Fla. Ga. Md. N. C. S. C. Va. W. Va.	15,774,473	12	67	123	83	169,116	847,932	348	537,981	1,550,185	189
North Central states Ill. Ind. Ia. Kan. Mich. Minn. Mo. Neb. N. D. O. S. D. Wis.	38,533,038	13	155	234	52	581,051	1,563,441	169	1,032,970	5,088,066	164
South Central states Ala. Ark. Ky. La. Miss. Okla. Tenn. Tex.	22,047,229	15	59	115	94	209,226	650,875	201	751,588	1,427,020	89
Western states Ariz. Calif. Colo. Ida. Mont. Nev., N. M. Ore. Utah Wash. Wyo.	11,885,058	33	54	129	143	190,481	697,584	267	605,185	1,654,574	269
Totals in United States	122,698,190	16	678	1,027	51	3,000,163	6,644,983	121	9,522,123	19,056,394	100

mately that for 1921. The tremendous growth of this type of medical service is apparent.

In the 131 special outpatient departments reporting for 1929, there was a total of 626,574 patients who made a total of 1,339,984 visits.

The striking fact is that while in 1921 one person out of every 35 in the United States visited an outpatient department at least once during the year, in 1929 no less than 1 out of every 18 made such a visit. If the patients visiting other dispensaries were included, the ratio would, of course, be smaller still.

RATIO OF GROWTH OF OUTPATIENT DEPARTMENTS
TO INCREASE OF POPULATION

The conclusion that these figures only correspond to the growth of population is confuted by the following table:

	1921	1929	Per Cent Increase
Population of United States	10,710,670	122,698,190	16
Outpatient departments in hospitals of United States	678	1,027	51
Number of patients treated	3,000,163	6,644,983	121
Number of visits made	9,522,123	19,056,394	100

Thus we find that while the total population has grown only 16 per cent, the number of outpatient departments of hospitals has been increased by 51 per cent, 121 per cent more patients were treated in these clinics, and 100 per cent more visits were made in 1929. Furthermore, this remarkable increase in the number and use of these facilities has taken place in the short space of eight years.

The number of outpatient departments of the hospitals in 1921 and in 1929 and the work done by them is summarized according to states in table 15. This shows Pennsylvania with the greatest number and New York with the next greatest.

In the summary according to geographic districts as shown in table 16, the figures warrant comparison.

It is apparent that hospitals in the Western, South Central and South Atlantic states have been organizing

other words, hospitals are no longer confined to the large cities, and the growth of the outpatient departments has simply followed that of the hospitals.

OUTPATIENT DEPARTMENTS IN TWENTY-FIVE
LARGEST CITIES REPORTED INCREASES
IN PATIENTS AND VISITS

Table 17 shows that 269 general outpatient departments of hospitals, or 26 per cent of the total, are located in the twenty-five largest cities of the United

States. New York reports the greatest number, Philadelphia the second greatest, and San Francisco, third. In the number of patients treated, Pittsburgh is in third place and in the number of visits in the Boston is in third place.

TYPE OF SERVICE RENDERED

Of the hospitals reporting, 707 have divided their outpatient departments into various clinical services, the remaining 320 are not departmentalized. There is undoubtedly a growing tendency in the former direction. The thirty clinical divisions listed in the questionnaire have been condensed into nine main groups, as follows:

Medicine	Surgery	Obstetrics
Cardiac	Accident and emergency	Gynecology
Dermatology	Ear, nose, throat	Prenatal
Diagnosis	Eye	Postnatal
Gastrointestinal	Genito-urinary	
Mental	Orthopedics	
Metabolism	Proctology	
Allergy		
Pediatrics	Tuberculosis	Physical therapy
	Nutrition	Electrotherapy
		Hydrotherapy
		Massage
Veneral	X-ray	Dentistry

The number of outpatient departments conducting such clinical departments, the patients treated, and the visits, are collected in the following table:

	Number	Patients	Visits
General service (records not kept by departments)	370	1,563,104	3,866,642
Medicine	548	1,033,299	3,649,903
Surgery	548	2,661,730	7,611,166
Obstetrics and gynecology	418	293,331	1,087,380
Pediatrics	426	260,628	841,410
Physical therapy	239	2,090,111	1,908,003
Tuberculosis	277	119,348	331,018
Veneral diseases	201	99,096	631,888
X-ray	393	601,007	576,910
Dentistry	319	251,453	630,144
Total	3811	1,041,161	20,110,119

SOCIAL SERVICE

In answer to the question as to who determines the ability of the patient "to pay reasonable charges for the services of a private physician," 762 replies were received, leaving out of account 220 answers from federal, industrial and charitable institutions. The 762 replies ran as follows:

Social service	538
Physician	164
Charities	12
Superintendent	8
Governing board of hospitals	6
Court	2
Manager of hospital	1
No one responsible	31
Total	762

In 1921 only 380 general dispensaries (including those outside of hospitals) employed social service workers, as against 538 in 1929. Evidently hospital administrators are coming to the conclusion that the determination of the patient's ability to pay is a function of the social service department.

CONCLUSIONS REGARDING OUTPATIENT DEPARTMENTS

1. There has been a tremendous growth in the number and in the use of the outpatient departments.
2. The Western states report the greatest number of new departments organized, but the rate of growth is greatest in the South Atlantic states.
3. Outpatient departments are becoming departmentalized.
4. The social service worker determines the patient's ability to pay in the majority of instances.

Following is a summary of statistics covering both the hospitals and sanatoriums and the related institutions:

	Hospitals	Beds	Bassinets	Average Patients
Hospitals and sanatoriums	5,441	898,042	47,392	724,943
Related institutions	1,375	57,827	2,192	38,439
Totals registered	6,816	955,869	49,584	763,382

CLASSIFICATION

(a) *Hospitals and Sanatoriums*, (b) *Related Institutions*—In this issue for the first time the list of hospitals registered by the American Medical Association, beginning on page 1023 is given in two sections, (a) 5,344 hospitals and sanatoriums, and (b) 1,375 related institutions.

The related institutions, because of their special or limited nature, do not deserve to be regarded as hospitals but are, so far as we know, entirely ethical and render a needed nursing or medical service to their communities.

Among the related institutions will be noted some that bear the name of general hospitals. The majority of these have been found lacking in some of the services that are usually found in a general hospital. Among the essential features, one or more of which is usually lacking in these small institutions, are adequate laboratory service, staff organization, radio logic service, record system, and consultation to safeguard the best interests of patients.

Among the 6,719 institutions appearing on the register are 5,344 hospitals having a capacity of 898,042 beds and 1,375 related institutions with a total capacity of 57,827 beds.

HOW THE FACTS WERE OBTAINED

The figures shown in these articles were obtained through (1) reports made by the hospitals themselves using a simple form which is ordinarily filled out in the superintendent's office and signed by the superintendent, (2) verification, where necessary, and additional facts, if desired, obtained by special correspondence and by inspection, (3) a printed proof of hospital data for the American Medical Directory submitted to each hospital for verification, and (4) finally the list of hospitals sent to the Association's county correspondents and district councilors and others, thus obtaining additional facts and verification from reliable sources outside the hospitals.

The response of hospitals in cooperating with the Association to make the census as complete as possible has been very gratifying.

HOSPITALS REFUSED REGISTRATION

Not included in any of the lists or statistics in this issue are 540 institutions which because of alleged unethical or criminal practices, admission to their staffs of members who are seriously unqualified, either morally or professionally, flagrant methods of advertising or for other valid reasons, are deemed unworthy of being included in any published list of reputable hospitals. The exclusion of such institutions from the Council's published lists marks the development of an aggressive campaign to establish safeguards against irresponsible or malicious institutions which are a menace to the public. For these reasons, therefore, they are excluded from the lists of institutions held out as worthy of receiving the public's patronage. The 540 unregistered institutions have only 14,142 beds.

TYPE OF SERVICE RENDERED

Of the hospitals reporting, 707 have divided their outpatient departments into various clinical services, the remaining 320 are not departmentalized. There is undoubtedly a growing tendency in the former direction. The thirty clinical divisions listed in the questionnaire have been condensed into nine main groups, as follows:

Medicine	Surgery	Obstetrics
Cardiac	Accident and emergency	Gynecology
Dermatology	Ear nose throat	Prenatal
Diagnosis	Eye	Postnatal
Gastro intestinal	Genito urinary	
Mental	Orthopedics	
Metabolism	Proctology	
Allergy		
Pediatrics	Tuberculosis	Physical therapy
	Nutrition	Electrotherapy
		Hydrotherapy
		Massage
Venerical	Ray	Dentistry

The number of outpatient departments conducting such clinical departments, the patients treated, and the visits, are collected in the following table:

Hospital	Type of Service	Control	Beds	Average Patients	Businesses	Outpatient Dept	Supt. R.N. Layman	Year Est

Following is a summary of statistics covering both the hospitals and sanatoriums and the related institutions:

	Hospitals	Beds	Businesses	Average Patients
Hospitals and sanatoriums	5,344	898,012	47,392	724.94
Related Institutions	1,375	57,827	2,192	28.49
Totals registered	6,719	955,839	49,584	763.43

CLASSIFICATION

(a) Hospitals and Sanatoriums, (b) Related Institutions—In this issue for the first time the list of hospitals registered by the American Medical Association, beginning on page 1023 is given in two sections (a) 5,344 hospitals and sanatoriums, and (b) 1,375 related institutions.

The related institutions, because of their special or limited nature, do not deserve to be regarded as hospitals but are, so far as we know, entirely ethical and render a needed nursing or medical service to their communities.

Among the related institutions will be noted some that bear the name of general hospitals. The majority of these have been registered by the American Medical Association.

NOTE—The foregoing list contains the names of 6,719 hospitals admitted to the Hospital Register of the American Medical Association. It omits the names of 540 institutions which after investigation, were not accepted. Hospitals approved for internship are marked with a five-point star (*) those approved for residencies in specialties, or advanced internship, with a plus sign (+). Copies of the essentials or standards, for the (1) registration of hospitals, (2) approval for internship, and (3) approval for residencies in specialties, as well as other information about the hospital work of the American Medical Association, can be obtained by writing to the Council on Medical Education and Hospitals of the American Medical Association 535 North Dearborn Street Chicago. Copies of the hospital data and the list pages 991 to 1088, in special binding, are available at the price of 50 cents per copy.

Schools of nursing accredited by their respective state boards are marked with a black dot (•). Information regarding the accrediting of those schools is supplied by state boards of nurse examiners at the capitals of the respective states. Great care has been taken to make the material in this issue accurate. Corrections will be welcomed.

SATURDAY, MARCH 28, 1931

THE INCREASING IMPORTANCE OF HOSPITALS

The tenth annual compilation of statistics regarding hospital service in the United States, presented this week in THE JOURNAL, brings fresh interest to a consideration of the magnitude of hospital service. Not long ago, hospital procedures were the business only of the few who worked within their walls. The change to modern methods has been so sweeping as to seem inevitable. A comparison of hospital service of ten or twenty years ago with that of today arouses pride in the mighty forces that have brought about such changes.

HOSPITALS AND MEDICAL EDUCATION

The service of hospitals in the teaching of medicine has become a matter of primary importance. A modern medical school can hardly be conceived of apart from hospitals. There are in the United States 76 acceptable medical schools, but there are 316 teaching hospitals. These teaching hospitals, with a total bed capacity of 135,548, are affiliated with the 76 medical schools for teaching purposes and make the high quality of the clinical service in these schools possible.

But such a statement leaves more than half of the story untold. After the completion of four years of study in the medical schools, 664 approved hospitals, with a total bed capacity of 201,974, wait to receive the army of medical students, with an offer of 5,584 internships for their practical training in the care of the sick. And to those who, now trained in general medicine, desire to pursue some special branch of medical study, another group of 349 hospitals, with a total bed capacity of 218,495, offer 2,069 approved residencies in the various specialties.

There is still another chapter to the story that cannot be told in figures. Adequate statistics are not available regarding the large number of hospitals offering postgraduate courses—courses designed to keep efficient the well trained army of practitioners whose contacts with medical schools are now matters more of past than of current history. The clinics held

singly rather than in courses constitute another unknown but important factor in this phase of hospital service.

INCREASING USE OF HOSPITALS BY PHYSICIANS

The practice of medicine also is being transferred to hospitals in a continuously increasing degree. In 1909 there were in the United States 4,359 reasonably acceptable hospitals, in 1930 there were 6,719, a numerical increase of 2,360, or 54.1 per cent. But the bed capacity of these hospitals rose during the same period from 421,065 to 955,869, a capacity increase of 534,804, or 127 per cent.

Approximately two thirds of the active physicians of the United States are now connected with hospitals. In 1929 there were 152,503 licensed physicians, about 10,000 of whom were not in practice. Of the 142,500 who were in practice, 98,491 were connected with hospitals as staff members, superintendents, residents and interns. The physicians of ten or more years ago were not so connected to any such extent. Indeed, the increased use of hospitals has proceeded with and has been largely due to the increase in connection of physicians with the hospitals. If the present trend continues, the number of active physicians not connected with hospitals will be infinitesimal.

The greatest number of those not yet participating in hospital practice are among the general practitioners. Hospital connection has become a practical necessity to the specialist and has increased with the growth of specialization. In 1929 the numbers of practitioners in the various specialties were

Internists	3,378	Obstetricians & gynecologists	6,108
Surgeons	12,939	Orthopedists	810
Neuro-psychiatrists	1,973	Ophthalmologists	1,311
Radiologists	1,653	Otorhinolaryngologists	6,505
Dermatologists	890	Specialists in tuberculosis	983
Pathologists	672	Urologists	2,249
Pediatricians	3,503	Other specialists	1,972

These practitioners make the hospitals what they are and in turn depend on them for their economic and professional lives. Every specialty therefore has a claim on these hospitals—a logical and undeniable right to a voice in the determination of hospital plans and procedures. The interests of no one specialty are paramount, the solution of hospital problems is the common task of all.

The best judge of hospital service in any special field is obviously the specialist in that field. Who could help more to develop a hospital's facilities for obstetric practice than a properly qualified obstetrician? Who is a more proper person for planning a first class roentgen-ray department than the roentgenologist? To whom can one look for the highest degree of efficiency in the treatment of nervous and mental disorders if not to the psychiatrist?

FEDERAL AND STATE HOSPITALS

Federal and state governments are entering into competition with private agencies in the hospital field.

to a constantly increasing extent. In 1909 there were 232 state hospitals in the United States, in 1930 there were 581, a numerical increase of 150.4 per cent. In 1909 the bed capacity of state hospitals was 189,049, in 1930 it was 405,309, a capacity increase of 114.3 per cent. In 1909 there were 71 federal hospitals in the continental United States, in 1930 there were 288, a numerical increase of 305.6 per cent. In 1909 the bed capacity of federal hospitals was 8,827, in 1930 it was 63,581, a capacity increase of 620.3 per cent.

Such strides in the building and enlarging of hospitals by federal and state governments may be interpreted in either of two ways: one may see in it a belated recognition of civic duty in the matter of chronic cases where family financial support fails, or one may view it as a preparatory step in a policy of unlimited expansion whose ultimate goal is state medicine.

That improvements in the way of scientific equipment for the care of the sick have kept pace with the expansion in the capacity of hospitals is shown by the fact that from 1923 to 1930 the number of laboratories in hospitals increased from 3,035 to 4,249. During the same time the number of x-ray departments increased from 2,841 to 4,523. The departments of physical therapy in hospitals numbered 2,091 in 1927 and 2,236 in 1930. And along with the increase in the number of these adjuncts to diagnosis and treatment in hospitals has come increased demand that these departments be under the supervision of medical practitioners who are specially qualified.

GROWTH OF OUTPATIENT SERVICE

The outpatient service of hospitals has grown steadily in recent years. Indications are that this growth has been influenced more by the tendency to congregate in cities than by the increasing density of population in general. In 1921, 678 hospitals reported that 3,000,163 outpatients made 9,552,123 visits to the outpatient department. In 1929, 1,027 hospitals reported that 6,644,983 outpatients made 19,056,394 visits.

INTERDEPENDENCE OF HOSPITALS AND PHYSICIANS

The greater the development of such institutions as have been described, the more extensive their use by the people, the more active must become the interest of the physician in their direction and control. It seems so simple to leave the economics, the construction, the administration of hospitals to lay boards and superintendents that far too many physicians are content simply to have the hospital as a work place ready for them and their patients. Thus the attitude has grown among many philanthropists and hospital workers that the physician is the recipient of these facilities from the public and must therefore be under their direction. Nothing could be more fallacious. The doctors make the hospital. Without them it necessarily fails. Its merits are equivalent to their merits and cannot surpass them. This fact should be realized by lay directors who should take their medical staffs into

consultation on every matter affecting the welfare of the institution and be guided by them in every scientific problem.

COLORADO SUNSHINE

So much is said nowadays about the dearth of sunshine and its consequent detriment to human well being that it is interesting to discover some of the regions where nature's beneficent sun rays are always available in abundance. The existence of seasonal variations and their effects on the incidence of infantile rickets have been repeatedly stressed in recent years. For example, Tisdall and Brown¹ found the antirachitic effect of sunshine at Toronto in April and May to be approximately eight times as great as in December, January and February. Day² recently reported a seasonal variation in the antirachitic potency of Arkansas sunshine. He found that whereas an average daily exposure to sunshine of ten minutes over a period of forty days during June and July was sufficient to induce calcification in rats fed a rachitogenic diet, incomplete protection against rickets resulted from two and one-half hours' daily exposure to sunshine in January and February. According to Hess,³ in the tropics rickets is almost unknown, occurring merely in mild form or in cases in which the infant has been confined indoors for a long period. It will be found that the intensity of rickets throughout the world corresponds fairly closely to the amount of sunshine. When one bears in mind the varying diet of the peoples in the different parts of the world represented by these centers of population, he adds, the dominance of sunlight in the etiology of rickets is most striking. The fact that rickets, osteomalacia and tetany develop in India, where the women are deprived of the benefit of the tropical sunshine by observing the system of purdah, emphasizes still more strikingly the dependence of rickets and cognate clinical conditions on exposure to the sun's rays. Hess has pointed out further that the dominant factor in regard to the antirachitic activity of the solar rays is not so much the number of hours of sunshine as its quality and intensity. These properties go hand in hand.

Colorado has long enjoyed the reputation of having a salubrious climate. Recent experiments by Lewis and his co-workers⁴ at the University of Colorado School of Medicine, Denver, indicate that the effective biologic rays of sunlight in June and July are quantitatively of a greater magnitude in Colorado than in any of the other places where the antirachitic effect of sunlight

3 Hess A. T. Rickets Including Osteomalacia and Tetany. Philadelphia: Lea and Febiger, 1929.

4 Stein H. B. and Lewis R. C. Rickets. The Comparatively High Value of Colorado Sunshine in Its Prevention. *Am. J. Dis. Child.* 41: 62 (Jan.) 1931. Lewis R. C., Frumess G. M. and Stein H. B. A Comparison of the Antirachitic Effects of Winter and Summer Sunshine in Colorado. *ibid.* 41: 71 (Jan.) 1931.

has been studied. They believe that the relative freedom of the atmosphere from moisture and smoke offers satisfactory explanation of the comparatively high antirachitic potency of Colorado sunshine. The observations on experimental animals are supported by records of a comparatively low incidence of rickets in Colorado.⁵ Another striking feature is the demonstration that there is no great difference in the antirachitic effect of winter and of summer sunshine in Colorado. Elsewhere sunshine may vary. Climatic variabilities have assumed significance in a new way in present day medicine. They furnish an illustration, says Hess, of what we have recently become sensible of in regard to nutrition—the lack of relationship, one may almost say the inverse relationship, between abundance of supply and indispensability of food constituents. The vitamins furnish a striking example of this principle. The law of “the vital importance of the minimum” applies to the radiations of the sun—those rays which are furnished in smallest amount and in least intensity are nevertheless most indispensable.

THE ETIOLOGY OF HODGKIN'S DISEASE

Negative results in research are not nearly so exciting as positive, but they are important and, unfortunately, seem to have a higher average of reliability than most of the results reported as positive. A particularly important report of negative results has recently been published under the title of the etiology of lymphadenoma, a summary of six years' researches, by C. C. Twort,⁶ pathologist to the Manchester Committee on Cancer. By lymphadenoma is meant what most American physicians usually call Hodgkin's disease and what Germans often designate as lymphogranulomatosis, one of many striking illustrations of the distressingly confused conditions of medical nomenclature. The importance of the report lies in the fact that it is based on an extremely careful study by many methods on a large amount of material, sixty-one cases positively identified by the presence of typical “lymphadenoma giant cells,” and twenty-one cases either probably or possibly lymphadenoma. Most pathologists who have struggled with the diagnosis of biopsy sections from lymph nodes will be gratified by the fact that after six years of special study Twort is compelled to state that “there appears to be no single feature which permits one to diagnose lymphadenoma with certainty.” He ventures the observation “Besides the presence of lymphadenoma giant cells and the eosinophil cells, mitosis of the various cells outside the germinal centers, in a gland free from hemorrhages, appears to be an important diagnostic point.”

Despite a vast number of experiments by many methods it was not found possible to demonstrate consistently any specific animal or vegetable parasite in the

disseminated tissues. Cultures of lymph nodes removed before death were in almost all instances sterile, and it was not possible to repeat “the positive animal infection experiments which many other workers have been fortunate enough to obtain.” The ameba of Kofoid and the granular tubercle bacillus of Fraenkel and Much could not be found, nor could the diphtheroid organisms of Bunting and Yates be cultivated. Tissues from forty cases microscopically free from tuberculous lesions were injected into 150 guinea-pigs without a single animal developing tuberculosis. Indeed, in this series there seems to have been much less association with tuberculosis than most pathologists have observed, for, in the eighty-two cases of certain, probable or possible lymphadenoma, tuberculosis was absent in all antemortem specimens and present in but three of the twenty-seven necropsies.

It is unfortunate that inoculation experiments could not have been carried out with monkeys and apes and that no inoculations were made in fowls, in view of the suggestion of L'Esperance⁷ that Hodgkin's disease is a form of avian tuberculosis in man. It is recorded that the patients who were tested with tuberculin gave negative reactions. An assortment of other *in vivo* and *in vitro* experiments gave absolutely barren results. Twort says that the different experimental procedures so invariably led to nothing that one might have been dealing with a true new growth “instead of what is generally accepted as a granuloma.”

Current Comment

ALLERGIC ABSORPTION RATE

It is a tempting clinical hypothesis to assume that certain individuals develop allergic syndromes because of hyperpermeability of exposed mucosae, normal individuals remaining free from symptoms because of adequate resistance to absorption of protein. This simple mechanistic theory of allergy, however, is without experimental foundation. Drs. Cohen, Eckel, Briethart and Rudolph⁸ of the Western Reserve University Institute of Pathology, in attempting to supply such experimental evidence, unwittingly demonstrated the exact opposite—an increased resistance to alien protein absorption through hypersensitive mucosae. A similar paradox was previously reported by Brunner and Walzer.⁹ Studies of protein absorption through exposed mucosae are made possible by the application of the Prausnitz-Kustner technique, involving passive sensitization of local skin areas by intracutaneous injection with allergic or atopic human serum, control injections being made with normal human serum. Twenty-four hours after local sensitization to ragweed protein the Cleveland investigators blew ragweed pollen into the nostrils of their normal individuals, care being taken

⁹ Brunner Matthew and Walzer. Maternal Allergy to Ragweed Proteins in Human Being. *Arch. Int. Med.* 44: 172 (Aug.) 1930.

to prevent swallowing. Within from fourteen to thirty minutes local itching was experienced in the sensitized skin areas, followed by redness and the formation of wheals, no reaction taking place in control areas injected with normal human serum. Similar tests on allergic individuals—none of them, however, sensitive to ragweed protein—showed a markedly delayed protein absorption, the formation of wheals never taking place sooner than forty-seven minutes, many of the allergic individuals showing no Prausnitz-Kustner reaction by the end of two hours. Subsequent tests on these non-reacting individuals showed the local skin areas still specifically hypersensitive. The conclusion was drawn that the allergic mucosa is provided with a protein-capturing mechanism, conceivably similar to the local protein-fixation mechanism demonstrated by Opie¹⁰ in hypersensitive rabbits. Since "every one living in the ragweed belt absorbs sufficient [ragweed pollen through the nasal mucosa] to develop sensitivity if the other conditions are suitable for its development," the etiology of allergy must be referred to hereditary tendencies, developmental subfunctions, embryonic reversions and other current hypotheses.

CONTRIBUTIONS FOR MEDICAL SALON IN PERSHING HALL

The sum contributed this week for the Pershing Memorial in Paris brings the total to \$2,215.60. A list of those who have contributed during the current week follows:

O. S. Werner, M.D., Cambridge, Minn.	F. L. Hawkins, M.D., Meredith, N. H.
W. O. Arnold, M.D., West Palm Beach, Fla.	F. S. Kent, M.D., Burlington, Vt.
A. W. Schreiber, M.D., La Fayette, Ind.	William T. Coughlin, M.D., St. Louis
	E. M. Mikkelsen, M.D., Chicago

THE PHILADELPHIA SESSION

Special Exhibit on Fresh Pathology in the Scientific Exhibit—Guest Demonstrators

Announcement is made of the appointment of the Committee on Fresh Pathology Exhibit for the 1931 Session of the American Medical Association. The committee consists of Drs. J. T. Bauer, Ayer Laboratory, Pennsylvania Hospital; E. A. Case, professor of pathology, University of Pennsylvania Graduate School of Medicine; J. H. Clark, director of laboratories, Philadelphia General Hospital; R. P. Custer, department of pathology, University of Pennsylvania; John Eiman, department of pathology, Presbyterian Hospital; John I. Fanz, professor of pathology, Temple University School of Medicine; Herbert Fox, director of Pepper Laboratory, University Hospital; Baldern Lucke, associate professor of pathology, University of Pennsylvania School of Medicine; V. H. Moon, professor of pathology, Jefferson Medical College; Stanley Reimann, department of pathology, Lankenau Hospital; Russell Richardson, professor of pathology, Methodist Hospital; G. M. Robson, department of pathology, University of Pennsylvania School of Medicine; and I. T. Zeckwer, department of pathology, University of Pennsylvania School of Medicine. Dr. E. B. Krumbhaar, professor of pathology, University of Pennsylvania School of Medicine, has consented to accept the appointment of chairman of this committee.

The committee has made arrangements for securing ample surgical and necropsy material from the chief hospitals in Philadelphia, including the Philadelphia General Hospital which alone averages over twenty necropsies a week. The members

of the committee representing different hospitals have generously placed at the disposal of the committee anything that may be of interest at the respective institutions. The members of the Local Committee on Fresh Pathology will also take part in various demonstrations throughout the session week except during the schedules for the guest demonstrators.

Following the plan adopted last year, guest demonstrators will be a feature of the Fresh Pathology Exhibit again this year. The guest demonstrators and their general topics will be as follows:

Dr. Frank W. Hartman	Detroit	Pathology of the Kidney
Dr. Howard T. Karsner	Cleveland	Pathology of Heart Disease
Dr. James P. Simonds	Chicago	Pathology of the Gastro-Intestinal Tract and Liver
Dr. Milton C. Winternitz	New Haven	Pathology of the Lungs and Blood Vessels

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10 45 on Tuesday, 9 15 on Thursday and 10 30 on Saturday over Station WBBM (770 kilocycles or 389.4 meters).

The program for the week is as follows:

March 30	Mental Health Slogans
March 31	Our Smoky Cities
April 2	The Shoe of Tomorrow
April 4	Big Medicine

Five minute health talks may be heard over the Columbia Broadcasting System daily, except Sundays and holidays, from 12 to 12 05 p. m., Central Standard Time.

The program for the week is as follows:

March 30	The Lady and the Fashions
March 31	University Health Officer Speaks—Keeping the School Child Well
April 1	What Drinking Fountain Is Sanitary?
April 2	Cancer of the Mouth
April 3	We Speed and We Die
April 4	Chemistry Aids Medicine

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SEPARATING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Hospital News—New clinical and research laboratories at Mount Zion Hospital, San Francisco, were formally opened, January 23. Dr. Leo Buerger gave an address on "Thrombo-Angiitis Obliterans." The director of the research institute and clinical laboratories is Dr. Frederick Ebersson, assistant professor of medicine at the University of California Medical School. A new department of pathology has been established under the direction of Dr. Glenville Y. Rusk, professor of pathology, University of California. The cornerstone of the new Los Angeles County General Hospital was laid Dec. 7, 1930 (THE JOURNAL, June 4, 1927, p. 1817).

Society News—The eighty-fourth semiannual meeting of the Southern California Medical Association will be held in the Hotel Del Coronado, Coronado Beach, April 10-11. Guest speakers will be Drs. Walter C. Alvarez, Rochester, Minn., on "Diagnosis of Gastro-Intestinal Diseases from the History"; Emile F. Holman, San Francisco, "Fundamental Principles Underlying the Treatment of Intrapulmonary Suppuration and Persistent Bronchial Fistula," and Francis de Groer, University of Leuven (Lemberg) Poland, "Diet in Fever." Papers will be given also by Drs. Francis M. Smith, San Diego, "Renal Insufficiency in Hypothyroidism"; Norman J. Kilbourne, Los Angeles, "Choice of Solutions in Injection Treatment of Varicose Veins"; Hugh T. Jones, Los Angeles, "Indications for the Choice of Conservative Surgery in Chronic Osteomyelitis"; Robert S. Smylie, Jr., San Diego, "Calcium Therapy in Acute Pelvic Inflammatory Disease," and Emil F. Tholen and William S. Kiskadden, Los Angeles, "Primary and Secondary Repair of Harelip."

¹⁰ Opie, E. L. J. Exper. Med. 39: 659 (May) 1924.

COLORADO

Bill Introduced—H 400 proposes a new act for the organization, construction, management and control of county public hospitals. It provides, among other things, that in the management of such hospitals no discrimination shall be made against the practitioners of any recognized school of medicine.

CONNECTICUT

Bill Introduced—S 209 proposes to provide that stillbirth certificates be signed by attending physicians and that in cases in which there are no attending physicians the certificates shall be signed by medical examiners.

GEORGIA

Society News—Physicians from New Orleans, Memphis, Dallas, Little Rock and other Southern cities organized the Southern Interurban Gynecological and Obstetrical Society in Atlanta, January 26. Speakers on the scientific program were Drs Charles B. Upshaw, on management of eclampsia; William F. Shallenberger, endometrioma; and Emmett D. Colvin, review of cesarean operations in Atlanta. Clinics were held at the Emory unit of Grady Hospital by Drs Upshaw and Rudolph A. Bartholomew. Dr James J. Clark addressed the Fulton County Medical Society, March 5, at Atlanta, on "Radiation Menopause in Treatment of Cases of Tetany and Angina Pectoris." Dr Lancelot Minor Blackford presented a clinical talk on "Functionally Two-Chambered Heart."

ILLINOIS

Bills Introduced—S 221 proposes to make the facilities of the state colony for epileptics available also for those suffering from "post encephalitis" or other mental diseases. S 231 proposes to provide for the licensing and supervision of child welfare agencies and boarding homes. S 234 proposes to regulate maternity hospitals and to provide for their licensing by the state department of health. H 484 proposes to prohibit the distribution in public schools of any printed, written or oral matter favoring any particular school or system of medicine or any special remedy purporting to confer immunity from disease or to effect a cure. H 515 proposes the issuance after examination of licenses to practice osteopathy and to practice surgery in all its branches, to applicants graduating from schools teaching osteopathy and surgery, which at the time of the graduation of such applicants require as a prerequisite to admission a four years' course of instruction in an accredited high school and a two years' course in a college of liberal arts or its equivalent. Such applicants, in addition, must show evidence of twelve months' training in reputable hospitals or clinics. Present practitioners of osteopathy who have been in active practice for at least eight years, are graduates of osteopathic schools and have completed courses of instruction in surgery may take examinations for licenses to practice surgery in all its branches. For such practitioners the requirement relating to the successful completion of a two years' course in a college of liberal arts is waived. Under the present law, persons licensed to treat human ailments without the use of drugs or medicines and without operative surgery may take examinations in materia medica, therapeutics, surgery and obstetrics, and may receive licenses to practice medicine in all its branches if they pass such examinations but in order to be admitted to such examinations they must submit proof (1) of having completed in a medical college or a professional school teaching some system of treating human ailments, reputable and in good standing in the judgment of the department of registration, courses of instruction in materia medica, therapeutics, surgery, obstetrics and theory and practice deemed by the department to be equal to the courses of instruction required in those subjects for admission to the examination for a license to practice medicine in all its branches, (2) of a two years' course of instruction in a college of liberal arts, and (3) of at least twelve months training in a reputable hospital.

IOWA

Personal—Dr Daniel C. Steelsmith, who has been acting state commissioner of health since the death of Dr Henry Albert in April, 1930, has been appointed commissioner by Governor Turner.

Bills Introduced—S 334 proposes to appropriate \$30,000 annually to the state department of health for demonstrating and maintaining full time county health units. H 485 proposes to provide for the sexual sterilization of certain inmates of state institutions. H 499 prohibits the sale of food in any retail

establishment selling or offering for sale any poisonous or narcotic substances or fluids. H 490 proposes to create a board of examiners for suggestive therapeutics and to regulate such practice, defined as the treating of human ailments without the aid of surgery or drugs by means of human magnetical forces and human mental suggestion accompanied by the laying on of hands and physical manipulation.

MAINE

Bills Introduced—S 733 proposes that the superintendents of state hospitals for the insane may, in their discretion, receive all patients in need of special care and treatment. S 602 proposes that the supervision of public health nursing in schools in cities and towns and the work of public health nurses employed in schools shall be under the supervision of the state department of health through its division of public health nursing and child hygiene.

MARYLAND

Bills Introduced—S 198 proposes that, until 1936, no real estate held for future use and not for investment, by any hospital not organized or conducted for profit shall be subject to state county or municipal taxation. H 344 proposes to make it a misdemeanor for any person to experiment or operate in any manner whatsoever on any living dog, for any purpose other than the healing or curing of said dog.

Health Officer of Virgin Islands Appointed—Dr Charles H. Halliday, epidemiologist for the State Department of Health of Maryland for the past two years, has been appointed commissioner of health for the Virgin Islands by Gov. Paul M. Pearson. Dr Halliday, who was graduated from the College of Physicians and Surgeons, Baltimore, in 1904, was formerly epidemiologist of the California State Department of Health and for the Minnesota State Department of Health. He was engaged in public health work in the Philippine Islands and after the World War, spent a year and a half in typhus fever control work in Poland.

MASSACHUSETTS

Personal—Dr Eugene Walker, formerly assistant director of administration of the University Hospitals of Cleveland, has been appointed superintendent of Springfield Hospital to succeed the late Dr. Harold Waters Hersey.

The New Medical Center—Ceremonies marking the laying of the cornerstone for the New England Medical Center in which Tufts College Medical School, the Boston Floating Hospital and the Boston Dispensary will cooperate, were held January 26. Dr. Merritt H. Eddy, Middlebury, Vt., believed to be the oldest family physician in New England, was chosen to perform the ceremony of laying the cornerstone. The day was Dr. Eddy's ninety-eighth birthday. Dr. Alfred Worcester, Henry K. Oliver, professor of hygiene, Harvard University, gave an address. The center when completed will have three buildings: the Jackson Memorial Building of the Boston Floating Hospital, the Center building for clinics and quarters for nurses, and the dispensary building.

MINNESOTA

Bill Introduced—S 246 proposes that all persons who are now assistant pharmacists and who have been actively engaged as such since Jan. 1, 1927 shall be entitled to be registered as pharmacists without examination on application to the board of pharmacy and the payment of \$50.

MISSOURI

Gift of Old Prints—Dr. Makern B. Clopton, assistant professor of clinical surgery, Washington University School of Medicine, recently gave to the university a collection of more than 200 prints ranging from sixteenth century woodcuts to contemporary etchings. It is planned to establish an art center including a museum at the university. Included in the collection are a Rembrandt etching "The Three Crosses," a woodcut by Albrecht Dürer "The Mass of St. Gregory," four etchings by James McNeill Whistler, and an etching by Francisco Goya.

NEVADA

Bills Introduced—S 122 proposes to amend the medical practice act. Special meetings of the board are to be held at the call of the president or of not less than three members. Certificates by reciprocity may now be issued to (1) physicians of the United States unless they have declared their

intentions of becoming such or (2) persons who have not engaged in active practice for one year prior to the filing of their applications. It is also proposed that members of the board receive necessary traveling expenses and \$20 a day for time actually spent in the business of the board. The board is also authorized to employ investigators and necessary assistants. The expenses of the board must be paid out of the fees received by it and may never come out of the general fund of the state treasurer. Additional grounds for the revocation of licenses to practice medicine are also proposed. It is also to be a misdemeanor for any licensee to fail to furnish within ten days after demand by the secretary of the board a list of persons practicing the healing art in the licensee's office, or for any person willfully to make a false statement in a material regard in the affidavit required of applicants. S. 123 proposes to require the wardens or superintendents of state institutions to provide dental services for the inmates thereof. A. 225, to amend the osteopathic practice act, proposes (1) to define osteopathy as "that system of the healing art by which the operator treats the patient by manipulation of the body by the hands of the operator only" and (2) to provide that osteopathic physicians and surgeons shall have the same rights as physicians and surgeons of other schools of medicine, except that it shall be unlawful for them to prescribe or dispense any drugs or medicines or treat patients in any manner except as prescribed above.

NEW YORK

Society News—Dr. Thomas Parran, Jr., discussed the county health department and Dr. William H. Ross, public relations of a medical society at the Medical Society of the County of Nassau, Garden City, February 24.—Dr. Ernest E. Irons, Chicago, addressed the Buffalo Academy of Medicine, February 25, on "Facts and Fallacies Concerning Protein Therapy."

Bills Introduced—A. 1723 proposes to make it a misdemeanor to broadcast by radio any speech or remarks relating to medicine or using medical terms, or diagnosing any disease or ailment, or prescribing or recommending any form of medical or surgical cure, or any form of diet, unless the speaker is a duly licensed physician. S. 744, to amend the workmen's compensation act, proposes that compensation shall be payable for disabilities sustained or death incurred by an employee resulting from any occupational disease or illness which medical testimony establishes to be directly due to or caused by any employment coming within the act. A. 1855, to amend the compensation act, proposes to make compensable "fibrosis of the respiratory tract due to exposure to silica or rock dust." S. 1580 proposes that a certificate of birth of a child born in a hospital shall contain a photograph of the finger prints of the mother and the foot prints of the child, the impression of which shall be taken as soon after birth as is practicable.

New York City

Health Center in the Bronx—The first city built health center will be erected in the Bronx. The new building will be of stone and brick fireproof construction and will occupy the site at 349 East One Hundred and Fortieth Street, it will cost about \$175,000. Tentative plans provide for a three story building. The health center will be in about the center of population, as indicated by the schools and school registration.

University News—Gifts totaling about \$103,661 were given in January to Columbia University, it is reported. The Rockefeller Foundation gave \$51,000, of which \$36,000 is for studies of nutrition in Porto Rico, and \$15,000 for a study of compensation for automobile accidents now being conducted under the Council for Research in the Social Sciences. The Commonwealth Fund gave \$32,300 for dental research work. The General Education Board gave \$3,000 for a subdepartment of tropical medicine at the College of Physicians and Surgeons, and the International Committee for the Study of Infantile Paralysis, \$2,500 for the Milbank Paralysis Fund.

NORTH CAROLINA

Bills Introduced—S. 405, to amend the workmen's compensation act, proposes that a compensable disfigurement shall include the loss of any member or organ of the body for which no compensation is payable under the schedule of specific injuries set out in the act. H. 943, to amend the workmen's compensation act, proposes to provide that the compensation commission may at any time, on the request of an employee, order a change of physician and designate a physician suggested by the injured employee. S. 354 proposes that the North Carolina Board of

Health shall consist of nine members, four of whom shall be elected by the Medical Society of the State of North Carolina and five appointed by the governor. H. 975 proposes that the right to perform an autopsy on a dead human body shall be limited to cases (1) specially provided for by statute, (2) where so directed by the deceased, (3) where a coroner or the majority of a coroner's jury deem it necessary, on an inquest, and (4) where the husband or wife or one of the next of kin or other person charged by law with the duty of burial, in the order named and as known, shall authorize such autopsy.

OHIO

Bills Introduced—H. 541 proposes to require pharmacies to pay annual license fees, varying from \$5 to \$250. H. 588 proposes that on the approval of the county boards of health physicians in the proper and regular practice of their profession and in good faith may prescribe narcotic drugs for addicts in correctional treatment.

OKLAHOMA

Bills Introduced—H. 96 proposes to authorize the establishment of a state hospital for the Negro insane. S. 232 proposes (1) that hospitals shall have liens on patients' property brought therein for charges due for hospital fees, nursing, medical and professional services and (2) that it shall be a misdemeanor for any person to obtain hospital service with the intent to defraud hospitals of payment.

Fund for Research in Hematology—A fund was recently established at St. John's Hospital, Tulsa, by Mr. Mark Finston, Tulsa, for research work in hematology. The amount of the fund was not announced, but it is reported that additions will be made as conditions demand. It will be used to study blood changes in various diseases and the working out of specific problems in blood diseases. This is believed to be the first research fund established in Oklahoma.

PENNSYLVANIA

Society News—Drs. William A. Frontz and Charles A. Waters, Baltimore, addressed the Lycoming County Medical Society, March 13, on "Surgical Treatment of Cancer of the Prostate and Bladder" and "Radiation Therapy of Lesions of the Genito-Urinary Tract," respectively.—Dr. Herman Henry Van Horn addressed the Dauphin County Medical Society, March 3, on "Pathology, Diagnosis and Treatment of Blood Diseases."—Dr. Walter D. Hawkins addressed the Harrisburg Academy of Medicine, February 17, on diabetes mellitus.—Dr. Charles R. Reiners addressed the Huntingdon County Medical Society, March 12, on laboratory routine.—Dr. Russell L. Hyden, Cleveland, addressed the Cambria County Medical Society, March 12, on "Types and Treatment of Chronic Rheumatism."

Philadelphia

Health Department Positions Made Competitive—According to a recent ruling of the Civil Service Commission 557 positions in the city health department will be made competitive and subject to examination after March 31, it is reported. The positions affected are those paying more than \$1,000 a year. Seven of them are in the bureau of health, 264 in the Philadelphia General Hospital, 174 in the Hospital for Contagious Diseases, and 112 in the Philadelphia Hospital for Mental Diseases at Byberry.

RHODE ISLAND

Bill Introduced—H. 801 proposes to incorporate the osteopathic hospital of Rhode Island.

Society News—Dr. Stanley S. Freedman presented a "Review of Some Rare Diseases of Infancy and Childhood with Special Reference to Gaucher's Splenomegaly and Niemann-Pick's Disease" before the Providence Medical Association, March 2, and Drs. Ira H. Noyes, Bance Feinberg and Henry F. McCusker spoke on birth injuries.—The Joseph Samuels Dental Clinic for Children was dedicated, March 18, at the Rhode Island Hospital, Providence. Col. Joseph Samuels, founder of the clinic, was given a testimonial dinner on the same date by the Rhode Island Dental Society.

SOUTH DAKOTA

Bill Enacted—S. 37 provides that any person, who in 1927 had been engaged in the practice of pharmacy for one year shall have the right to registration under the requirements of the law enforced prior to 1927, provided such registration is completed before July 1, 1933.

TEXAS

Bill Introduced—H 846 provides for the commitment to a state, county or city hospital or to the county jail of persons addicted to the use of opium, morphine, heroin, coca leaves, cocaine, marijuana, or any preparation thereof

WASHINGTON

Society News—Dr Evans A Graham St Louis, addressed the King County Medical Society, Seattle, March 9, on the operative risk in patients with disease of the biliary tract. Drs Christian J Rohwer and Glenn G Grover spoke, March 2, on cerebral vascular lesions and paralytic ileus, respectively. —Drs Stephen T Parker, Jr, and Wilfred A Ash, Seattle, presented papers before a joint meeting of the Clallam and Jefferson county medical societies, February 19 on "Latent Cutaneous Syphilids" and "Medical Aspects of High Intestinal Obstruction," respectively

WISCONSIN

Bills Introduced—A 497, to amend the workmen's compensation act, apparently authorizes chiropractic treatments for injured employees. A 345, to amend that portion of the medical practice act which provides that three members of the examining board shall be allopathic, two homeopathic, two eclectic and one osteopathic, proposes that seven members of the board shall be practitioners of medicine and surgery and one member shall be a practitioner of osteopathy

GENERAL

Medical Subjects on Chemists' Program—At the eighty-first meeting of the American Chemical Society, Indianapolis, March 30-April 3, nearly 100 papers bearing on medical aspects of chemistry will be presented. Among the speakers and subjects listed on the program are Walter H Eddy, Ph D, vitamins; Arthur J Hill, Ph D, synthesis of local anesthetics; Dr Robert A Kehoe, chemical methods in the recognition, prevention and treatment of lead poisoning; Henry C Sherman, Ph D, and Miss Esther L Batchelder, quantitative measurement of vitamin A values; Arnold E Osterberg and Dr Ralph G Mills, osteoporosis associated with hyperthyroidism from the chemical standpoint; Shiro Tashiro, Ph D, and Leon H Schmidt, biochemical factors involved in the production of gastric ulcer; Edward F Kohman, Walter H Eddy, Ph D, and Celia Zall Gurin, a diet of canned food; and Donalee L Tabern and Elmer F Shelberg, physicochemical properties and hypnotic action of substituted barbituric acids

News of Epidemics—Newspapers reported, March 3, that smallpox was epidemic in Lima, Ohio, a city of 42,000, with 175 cases quarantined. The state health department reported that 400 cases had been quarantined in the state during January. —Measles, scarlet fever and diphtheria were epidemic in southern Illinois in February. Strict quarantine was imposed at New Athens and Harrisburg, school attendance was cut 25 per cent in West Frankfort, Benton and Herrin. According to the state health department, 8,024 cases of measles were reported in the state during the first nine weeks of 1931. —Seventy-five cases of smallpox were reported in Iowa for the week ended March 5, of these, 34 were in Scott County. —Three cases of cerebrospinal meningitis were discovered in Owensboro, Ky, February 20, four cases occurred in a high school in Columbus, Ohio, March 4. —Fourteen cases of smallpox were reported from Anderson, Ind, March 10. —Four cases of typhoid at Plymouth, Ohio, were attributed to the city water supply

Society News—The sixteenth annual meeting of the American Radium Society will be held in Philadelphia, June 8-9. Tentative plans for the program include symposiums on malignant growths above the clavicle, led by Dr Douglas Quick, New York, on carcinoma of the breast, led by Dr Burton J Lee, New York, and on malignant growths of the female genital tract led by Dr Henry Schmitz, Chicago. —At the annual meeting of the Southeastern Surgical Congress, March 9-10, in Atlanta, Dr Charles W Roberts, Atlanta, was elected president. Dr Frank K Boland, Atlanta, was made president-elect. Dr Alfonso J Mooney, Statesboro, vice president, and Dr Benjamin T Beasley, Jr, Atlanta, secretary. Speakers included Drs William Wayne Babcock, Philadelphia, "Vaginal Hysterectomy," Donald C Balfour, Rochester, Minn, "Present Status of the Management of Peptic Ulcer," Virray P Blair, St Louis, "Plastic Surgery" and Hugh H Young, Baltimore, "Differential Diagnosis and Management of the Senile Prostate"

The Shortage of Nurses

It is curious that in this period of unemployment there should be any shortage of labor in any calling. But the *Lancet* has appointed a commission to inquire into the reasons for the shortage of candidates for nursing the sick in general and special hospitals throughout the country and to offer suggestions for making the service more attractive for women suitable for this work. After an exhaustive inquiry the commission has presented an interim report. The reason most frequently put forward for the deficiency of nurses is the much wider sphere of women's work today. Many other occupations offer better salaries and better prospects with more freedom, more social amenities and without the restrictions and long hours of institutional life. For the solution of these difficulties some advocate 'living out' while others say it would be fatal to the profession. Superannuation schemes are advocated, others favor the reduction of menial work and the fixing of off-duty hours, so that the nurse can make social engagements. Some of the smaller hospitals attribute their difficulties to the fact that the training gained in them counts for nothing when the candidate enters an approved training school. Not many of the nursing authorities questioned believe in the lowering of the present educational standards but a number refer to the difficulty and disadvantages of combining ward with theoretical work, which makes the life of the probationer too arduous. To obviate this difficulty, preliminary training schools for some months before entering the wards are proposed. These would have the advantage of overcoming a problem continually put forward—the gap between the school leaving age and that at which the hospitals recruit. It is suggested that the education authorities might cooperate with the hospitals in the provision of schools for preliminary training in the theory of nursing. Under the present system the probationer is too tired by her ward work to take advantage of this training.

After training a difficulty is that the "staff nurse" regards her position as merely a stepping stone and immediately seeks a sister's post. Bound up with this difficulty is the opinion that, relative to the probationers, the trained staff nurses are underpaid. Finally the shortage of candidates is attributed to judging the profession by the conditions of the past and not by those of the present. An erroneous idea of overwork, underfeeding, and underpay exists and exaggerated reports of treatment by seniors remain in the minds of possible candidates and their parents. Propaganda for their correction is suggested.

The British Medical Association and Hospital Outpatients

In recent years a great increase has taken place in the number of hospital outpatients which reached a peak in 1911. Then owing to the national health insurance act and afterward to the Great War the number fell until 1920 when another increase began and continued until the number now exceeds that of 1911. In 1924 in 657 hospitals in England and Wales (excluding London), the number of new outpatients was 21,6770 and in 1928 the number had risen to 25,893,12. In the London hospitals the figure was 1,451,333 for 1921 and 1,760,807 for 1929. This rapid increase since the Great War may be partly explained by depression of trade. The British Medical Association has long contended that the primary object of the outpatient department should be for consultation and that it should undertake only such treatment as cannot be obtained from the doctor in private and that thus the more economical use of the subscriptions and of the time and energies of the medical

staffs would be promoted. The council of the association has made a report on the subject, in which the types of cases for which the outpatient departments are utilized are classified into four groups: (1) casualty cases, (2) chronic ordinary cases, (3) consultation cases, including those retained for special treatment, and (4) discharged inpatients. It is the chronic ordinary cases which are responsible for the bulk of the unjustifiable demands made on the medical staffs, and the council considers that a double check should be brought to bear on them. The patient should be examined but no treatment should be administered unless it is not available elsewhere. All patients not accepted for treatment should be referred to a private physician or (if the patient is insured) to an insurance physician, to a public medical service, to a provident dispensary, or to the public assistance officer, as the circumstances require. For complete success this procedure needs the active cooperation of the profession in the area from which the patients are drawn. In many instances all that will be needed is the one consultation, the patient being referred back to the source, with the diagnosis and suggestions for treatment. The primary object of the outpatient department should be for consultation. Except in cases of emergency, no person should be accepted for treatment in an outpatient department unless he brings a recommendation from a private physician, a provident or other dispensary, and a public clinic or public assistance medical officer.

The Prevalence of Cerebrospinal Fever

The ministry of health has issued a statement pointing out that periodic increases of cerebrospinal fever are not unusual. It was made generally notifiable in 1912, and from 200 to 300 cases were reported annually before the war. In the war years 1915-1917 there was an annual incidence in the civil population of from 1,300 to 2,500 cases. In 1928 the figure fell to 301, but since then the tendency has been upward. In the present year, 230 cases have already been reported in the civilian population and there is an outbreak among the soldiers in the garrison town of Aldershot. Of the cases now occurring about half are fatal. The meningococcus is found in the nose and throat passages of a large number of persons who remain well. Local outbreaks are favored by overcrowding in barracks and schools.

The Controversy over BCG Vaccine

The veterinarian Lignieres continues to pose, before the Academy of Medicine, as an ingrained opponent of the BCG vaccine of Calmette and takes every opportunity to attack it. He does not deny its efficacy and uses it himself on new born calves to protect them from tuberculosis. But he advises confining its use to the new-born menaced by tuberculous antecedents and living in a tuberculous environment. He contends that the bacilli of the BCG vaccine are susceptible, under certain circumstances, of regaining their virulence, for instance, when they are cultivated in a series on egg yolk. He invokes, furthermore, the observations made in Uruguay by Mr. Hormaeche, which, he alleges, prove that the reappearance of virulence is possible in the guinea-pig if the animal has been previously infected by the streptococcus. Whenever a communication is presented to the academy on the BCG vaccine, Mr. Lignieres takes the floor. Recently, the occasion was a communication from Prof. Leon Bernard announcing the favorable conclusions formulated by the international congress on tuberculosis on the use of the BCG vaccine. Bernard had to take a strong stand against the proposal of Lignieres that the conclusions be not accepted. A short time afterward, Lignieres renewed his attack when Calmette presented a new communication on the BCG vaccine. He spoke of the fatalities that occurred in Lübeck, alleging that the use of the vaccine is at

present prohibited in Germany. Calmette thereupon read to the assembly a letter from the minister of health of Germany affirming the contrary. Lignieres had to bow before this presentation of facts but continued to maintain that the vaccine could regain its virulence under certain conditions. Here upon Professor Viquez urged that, in order to settle the question definitely, a new series of experiments be instituted.

National Congress of Tuberculosis

The seventh *Congrès national de la tuberculose*, organized by the *Comité national contre la tuberculose*, the *Oeuvre de la tuberculose* and the *Fédération girondine des œuvres antituberculeuses* will be held in Bordeaux from March 30 to April 2, 1931. The officials in charge of the congress are Messieurs Calmette, Dopter and A. Honnorat, honorary presidents, Dean Sigault, president, Professors Leon Bernard, Bezançon, Leuret, Parisot, Sergent and Drs. Courcoux, Poix and Secousse, general secretaries, Commandant Le Bourdelles, Dr. Royer and Mr. Vovard, secretaries, and Mr. Georges Masson, treasurer. The topics on the program are: (1) "The Bacteriolysis of the Tubercle Bacillus," presented by Professor Bezançon, Dr. Philibert and Dr. Paraf (Paris), (2) "Diagnosis of Activity in Pulmonary Tuberculosis," presented by Professor Beuret and Dr. Crussimon (Bordeaux), (3) "How Can Pneumothorax Treatment Be Made Accessible to Indigent Patients?" presented by Dr. Küss (Paris), Drs. Secousse and Piechaud (Bordeaux), and (4) "Prophylaxis of Tuberculosis in the Army," presented by Lieutenant-Colonel Pilod and Commandant Le Bourdelles (Val de Grace). Addresses will be given by Dr. Burnand (Lusarne) on "Present Status of Treatment of Tuberculosis" and by Professor Sive (Barcelona) on "Advances in Phthisiology and Dispensary Practice."

International Congress of Radiology

The third International Congress of Radiology will be held in Paris, July 26-31. The following subjects are on the program: (1) "Radiologic Exploration of the Mucosa of the Digestive Tract," (2) "Radiologic Exploration of the Urinary Apparatus by the Use of Opaque Substances," (3) "Preoperative and Postoperative Treatment of Cancer of the Breast by Irradiations, with the Exception of Recurrences and Metastases," (4) "Radiotherapy in Inflammatory Disorders," and (5) "Diathermic Electrotherapy in Inflammatory Disorders." Plenary sessions including all the sections will be held for periods of thirty minutes on each of these topics. Typewritten summaries of communications (comprising at least 400 words), in French, English or German, should reach the secretariat by April 1 (122 rue La Boétie, Paris, VIIIe).

Sanitary Measures for the Approaching Colonial Exposition in Paris

Sanitary measures pertaining to the transportation and the sojourn in France of the natives who will participate in the Exposition coloniale, which is to open May 1, are contained in a special ministerial order. Every native will be provided with an individual health record card, which will show that he submitted to a medical examination before he embarked, that he received antismallpox, antityphoparatyphoid, antipneumonic, anticholera and antiplague inoculations, and also that he has undergone the delousing process, treatment for scabies, and intestinal disinfection. His card will show also his state of health during the voyage and before disembarkation, his health while in France, illnesses, hospitalizations, and the like. Every month the natives will be subjected to a medical examination for purposes of control and a final examination will be made at the end of their stay. The state of health during the return voyage and at the time of disembarkation in the colony will be noted on the cards. The supply of medicines to be taken on board for the 250 natives has been carefully selected.

NETHERLANDS

Feb 4, 1931

International Society for Study of Scientific Problems of Population

The purpose of the International Society for the Study of the Problems of Population is to bring together biologists, sociologists, economists, physicians, statisticians and statesmen for the study of the problems of population to determine the optimal population for the countries of the world for the different epochs. Every country has its delegates serving on committees. The Netherlands committee belongs to the active committees and numbers fifty five members. Professor Aalberse is founder and president, Prof Verrijn Stuart is vice president. There are three investigating committees, the second of which, that on the frequency of births, is presided over by Professor Methorst. The first committee is to study the relations between the food supply and the birth rate and is presided over by Professor Mees of Wageningen. The third committee has no program, having received no instructions as yet from the international commission. The second committee is investigating the subject of well being, mortality and the birth rate. The facts that have been collected seem to prove that the Netherlands is operating, in this respect, under favorable conditions. The Netherlands committee has received a subsidy of \$300 from the funds of the international association and a new subsidy is requested. Thus the future appears full of hope.

Administration of First Aid

The association Oranje Kruis organized in each province on the same day competitive tests for those who have had training in the administration of first aid in case of accident. These competitive tests have a twofold purpose: (1) to give to those who have pursued faithfully the course in the administration of first aid in case of accident an opportunity to demonstrate their ability, and (2) to allow the masses to learn from those who have studied the subject how easy it is to render first aid in an effective manner by the use of simple devices. The contest in each province included a contest for bearers of first aid in the strict sense of the word and a contest for those who have taken a course in the methods of saving drowning persons. The contests are open to everybody. Special sections of the contest were organized for the police, the firemen, the railway employees, men in charge of transportations of troops, and first-aid crews.

The Netherlands Society of Social Medicine

The Netherlands society of social medicine was founded at Amsterdam under the chairmanship of Dr Van der Hoeve. The purpose of the society is to promote on a large scale the study and the development of hygiene and social medicine, and the establishment of connections between physicians who, either privately or in connection with some service, are active in the domain of hygiene and social medicine. In addition to scientific meetings, the society purposes to continue the publication of *Tijdschrift voor sociale Geneeskunde*, which is the official organ of the association.

The Meat of Tuberculous Cattle

According to Hoefnagel, the sections of the law pertaining to the examination of meat should be subjected to revision, and especially the section that reads: "In the presence of milary foci in the lymph glands or parenchymatous organs, a recent blood infection must be admitted and the meat must be sterilized." According to some authors the presence of milary foci by no means justifies the assumption of a blood infection. There are some authors who consider that milary foci must be present in the kidneys to justify sterilization. According to the present law, the veterinarian must order the meat sterilized whenever a tuberculous animal presents, in addition to encysted foci in

the lungs even isolated milary foci in one or more of the organs. According to Hoefnagel, it would be better to change the law so that sterilization would be compulsory in the presence of milary centers in the kidneys. The advantages would be considerable and it would not injure the public health for from Chrenburg's experiences it is evident that the meat of tuberculous animals rarely contains the bacilli of tuberculosis.

BERLIN

(From Our Regular Correspondent)

Feb 16, 1931

Berlin's Need of Radium

Director Dr Schweers of the central bureau of health in Berlin in an address recently, discussed cancer treatment in Germany and in foreign countries. France has 51 Gm of radium, England 42 Gm, Sweden more than 6 Gm and Denmark more than 4 Gm. In Paris there is about 10 Gm and in New York, where the total number of deaths from cancer is not much higher than in Berlin about 13 Gm is available. In Germany the organization of cancer control is still in the beginnings. In Cologne the Allgemeine Ortskrankenkasse has established a large irradiation institute and in Berlin the sick benefit associations have a small supply of radium. For some time the city of Berlin has been working toward the organization of cancer treatment and an aid system for cancer patients. The treatment of cancer patients should be combined in a few large centers. The department for roentgen and radium treatment must always be the central feature of such an organization. Alongside of that department and with equal rights and privileges, must be the departments of surgery, gynecology, dermatology and other similar departments. The specialists needed for such departments are available in Berlin. The technical equipment for such cancer centers is however, still inadequate. The chief need is radium. The city itself has not more than 0.5 Gm, and even this small amount is distributed over six hospitals. In the Charite Hospital and in the university clinics there are only a few milligrams of radium. For the municipal institutions at least 2 Gm of radium must be procured at the start. Owing to the high cost of such an amount (about \$125,000) a municipal appropriation, under present conditions, is out of the question. Possibly the central government can be prevailed on to supply the deficiency. The radium problem is in reality a government matter, in order to prevent useless duplication and an increase in price as the result of a superfluous demand.

A Merger for the Prevention of Neoplastic Diseases

A merger for the prevention and combating of neoplastic diseases was recently created in Berlin by the league of sick benefit associations, the medical profession and the provincial bureau of insurance. All patients who are affected with neoplasms or are suspected of being so affected are to be notified as early as possible, on a special uniform blank to an aid center that is managed by a board composed of members chosen on a parity basis from the three constituent organizations and that is in charge of a physician selected by the league. The patients so notified will, when advisable, be examined as to their degree of disability by an expert selected by the management in the choice of whom the desires of the panel physicians will be considered as far as possible. The decision as to disability will take the form of an authoritative order. The medical supervision of the patients will remain in the hands of the attending panel physician unless certain special measures that he cannot carry out are indicated and after completion of treatment by a specialist or in hospitals the patient will return to the treatment of his physician. In accordance with the agreement of the sick benefit associations the right of changing the panel physician or the specialist is reserved to the patient. The

the business center will be creation and continual improvement of the record cards of patients, sociohygienic aid for the patients and their families seeking out of patients who avoid treatment or supervision, if need be institution of a demand for an authoritative order, negotiations with the competent insurance carrier with regard to the assumption of the costs, transportation, observance of the dates for control examinations, statistical elaboration of the record cards of patients. On the basis of the agreement as entered into, the panel physicians are urged to make the notification in every case and to work toward securing a definitive diagnosis.

Culture of Embryonic Human Heart Tissue

Before the Berliner Medizinische Gesellschaft, K. Hofer exhibited recently tissue cultures of a beating embryonic human heart, which had been obtained from a 68 weeks old human embryo through an operation on a myomatous uterus, from which the heart, still beating, was taken three and one half hours after the operation. Six cover glass cultures were implanted in a mixture of human plasma, chicken plasma and chicken embryo extract. The experimenters were able to preserve until the thirty sixth day the contractility of the heart tissue after repeated transfers to new culture mediums. Before the first transfer to a new culture, there were, in one culture, two distinctly different contraction rhythms, each of which involved one half of the explant. After the transfer, a smaller center had a rhythm of its own, more rapid than that of the remainder of the explant. If the temperature was kept constant (39 C), the number and the depth of the contractions remained from 50 to 68 contractions per minute. After a time, the contractions slowly decreased in number and depth. Cooling of the tissues impaired the contractility, until at room temperature a standstill resulted. The contractions were confined strictly to the original explant. The fibroblasts that appeared in large quantities within twenty-four hours showed no active contractions.

Origin of the Neuroglia

Prof. Del Rio Hortega, histologist, of Madrid, delivered an address before the Berliner Medizinische Gesellschaft, on the third element of the central nervous system. Hortega, who is a pupil of Ramon y Cajal, has devoted himself to the histology of the neuroglia. The place of origin of "the third element" is the pia mater, where this type of cell is found—especially in brains of the young—as circular objects with pseudopodia. From these microglia-cytes develop microglia cells, they have an oval nucleus and processes with many branches. On experimental application to the brain of a red hot needle, the microglia cells migrate in large numbers to the site of the lesion, and the red and the white blood corpuscles exert a phagocytic action. During this process, fat globules and iron pigment are much in evidence. The functional activity of the amoeboid motion and the phagocytosis correspond to the cells of the reticulo-endothelial system in the rest of the body. From that fact, and owing to the development from the meningeal polyblasts, the mesodermal origin of the microglia is assumed.

Marriages

ELIAS WEINER, Alexandria, La., to Miss Pauline Mossoff in Brooklyn, N. Y., March 8.

LORAIN E. TEGTMEIER to Miss Elvira Nold, both of Millstadt, Ill., February 11.

W. J. ROBINSON, Portia Ark., to Miss Belle Ketchum of Imboden, February 4.

BRUNO C. COOK, Fowler, Mich., to Miss Marie O'Leary of Detroit, in January.

ARTHUR C. REITIC to Miss Agnes Smith, both of Muncie, Ind., March 10.

Deaths

Wilder Judd Walker, Greensburg, Pa., Western Pennsylvania Medical College, Pittsburgh, 1900, member of the Medical Society of the State of Pennsylvania and the Associated Anesthetists of the United States and Canada, served during the World War, for many years member of the school board, on the staff of the Westmoreland Hospital, aged 56, died, February 26, of erysipelas.

Clara Marshall, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1875, formerly dean and emerita professor of materia medica and therapeutics at her alma mater, for many years on the staff of the Philadelphia General Hospital, aged 87, died, March 13, in the Bryn Mawr (Pa.) Hospital, of myocarditis and arteriosclerosis.

Louis Hicks Williams, Surg., Lieut. Commander, U. S. Navy, Chelsea, Mass., Johns Hopkins University School of Medicine, Baltimore, 1915, member of the American College of Surgeons, on the staff of the Naval Hospital, aged 40, died suddenly, February 18, in a hospital at Goldsboro, N. C., of encephalitis, following influenza.

William Taft Slayton, Morrisville, Vt., Baltimore Medical College, 1894, Harvard University Medical School, Boston, 1896, served during the World War, formerly member of the state legislature and state board of health, aged 61, died, March 3, in Miami, Fla., of chronic myocarditis.

Frederick J. Fielding, Chicago, Keokuk (Iowa) Medical College, 1896, on the staffs of the Lutheran Memorial Hospital and the Belmont Hospital, aged 64, died, March 9, of cerebral hemorrhage, as the result of a fall while trying to extricate a stalled automobile.

George F. Beasley, La Fayette, Ind., Rush Medical College, Chicago, 1864, member of the Indiana State Medical Association, Civil War veteran, formerly on the staff of St. Elizabeth's Hospital, aged 89, died, March 11, of myocarditis.

Arthur Pierre Latneau, Old Town, Maine, University of Vermont College of Medicine, Burlington, 1919, member of the Maine Medical Association, aged 36, died, February 3, in the Friendship Hospital, Bangor, of cholecystitis and appendicitis.

Richard Kuehne, Jersey City, N. J., Medical Department of Columbia College, New York, 1888, aged 79, died, February 14, in the North Hudson Hospital, Union City, of chronic interstitial nephritis, uremia and myocarditis.

Charles John Hood, Adrian, Mich., University of Michigan Medical School, Ann Arbor, 1887, member of the Nevada State Medical Association, aged 70, died, February 27, in Los Angeles, of coronary occlusion and duodenal ulcer.

Adellon P. Andrus, Ashland, Wis., Hahnemann Medical College and Hospital, Chicago, 1880, member of the State Medical Society of Wisconsin, aged 76, died, February 22, in the Ashland General Hospital, of heart disease.

Claude L. Sellers, St. Louis, St. Louis University School of Medicine, 1910, member of the Missouri State Medical Association, served during the World War, aged 46, was found dead, February 21, of a gunshot wound.

George Willard Treleven, Camp Borden, Ont., Canada, University of Manitoba Faculty of Medicine, Winnipeg, 1914, served in the Canadian Army during the World War, aged 41, died, February 11, of pneumonia.

Ulysses G. Williams, Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis, 1889, formerly county coroner, aged 66, died, January 13, of lobar pneumonia and epidemic encephalitis.

Noah R. Wenger, Fort Wayne, Ind., Cincinnati College of Medicine and Surgery, 1880, aged 78, died, February 11, in St. Joseph's Hospital, of injuries received when he was crushed by an automatic elevator.

Irving David Wilttrout, Chippewa Falls, Wis., Jefferson Medical College of Philadelphia, 1878, member of the State Medical Society of Wisconsin, aged 75, died, February 28, of myocarditis and angina pectoris.

John Gerin, Auburn, N. Y., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1872, formerly member of the city board of health, aged 61, died, February 15, of intestinal obstruction and influenza.

Arthur Campbell Kimball, St. Louis Medical Department of Washington University, St. Louis, 1903, on the staff

of the DePaul Hospital, aged 51, was found dead, February 3, of a self inflicted bullet wound

Samuel Nisley Traver $\oplus$ Harrisburg, Pa, Jefferson Medical College of Philadelphia, 1897, member of the American Urological Association, aged 58, was found dead, February 2, of a self inflicted bullet wound

Edwin Elmore Meyers, New Madison, Ohio, Eclectic Medical Institute, Cincinnati, 1889, aged 64, was instantly killed, February 14, when the automobile in which he was driving was struck by a train

Vincent Thomas Poole, Grantwood, N J, Marquette University School of Medicine, Milwaukee, 1913, member of the Medical Society of the State of New York, aged 39, died, in January, of pneumonia

Ernest Wellington Smith, Washington, D C Medical Department of Columbian University, Washington, 1908, aged 50, was killed February 1, near Fredericksburg, Va, in an automobile accident

Hallet B Hunt, St Paris, Ohio, Medical College of Ohio, Cincinnati, 1874, member of the Ohio State Medical Association, aged 84, died, February 9, of chronic interstitial nephritis and arteriosclerosis

Alexandre Ledoux $\oplus$ New Orleans, Medical Department of the Tulane University of Louisiana, New Orleans, 1891, aged 61, died, Dec 23, 1930, of coronary thrombosis and chronic myocarditis

James Hack Rush $\oplus$ Meridian, Miss, Mississippi Medical College, Meridian, 1910, aged 66, part owner of an infirmary bearing his name where he died, January 22, of chronic myocarditis

Philip Matson Thomas, Upperlake, Calif, Cooper Medical College, San Francisco, 1896, aged 58, died, Dec 23, 1930, in Los Angeles, of sclerosis of the coronary arteries of the heart

Otis Howard Bradley $\oplus$ Hudson, N Y, Medical Department of Columbia College, New York, 1889, aged 67, died, January 9, of angina pectoris and coronary thrombosis

Adelbert W Thorpe, Great Falls, Mont, St Louis College Physicians and Surgeons, 1895, aged 68, died, February 5 of carcinoma of the glands of the neck and hemiplegia

Calvin W Canan, Orkney Springs, Va, Baltimore Medical College, 1891, aged 65, was killed in February, when the automobile in which he was driving overturned

Howard Truman French $\oplus$ Deep River, Conn, Medical Department of Columbia College, New York, 1891, aged 64, died February 6, of coronary occlusion

George F Plew, Hymers Ind, Rush Medical College, Chicago, 1876, aged 82, died, February 17, of cerebral hemorrhage, nephritis and arteriosclerosis

John Thomas Loftus $\oplus$ Worcester, Mass, Harvard University Medical School, Boston, 1903, aged 63, died, February 4, of coronary embolism

Phebe Lininger, Springdale, Ark, Woman's Medical College, Kansas City, Mo, 1903, aged 77, died, February 5 of cerebral hemorrhage

Robinson Cox, Upper Stewiacke N S, Canada, Dalhousie University Faculty of Medicine, Halifax, 1875, aged 89, died, January 6

Jefferson R Huldrup, Windfall, Ind, Physio-Medical College of Indiana, Indianapolis, 1877, aged 86, died, February 5, of neuritis

Joel Cook, Orestes, Ind (licensed, Indiana 1897) health officer of Orestes for many years, aged 75, died, in February, of arteriosclerosis

Horace Curlin Hall, Laredo Texas University of Texas School of Medicine, Galveston, 1898, aged 57, died, February 2 of myocarditis

Robert Greenlee Baird, Sharon Pa Cleveland Medical College, Homeopathic, 1897, aged 64, died January 14, of heart disease

Albert John File, Ameliasburg, Ont Canada, Queen's University Faculty of Medicine, Kingston, 1869, aged 88, died January 6

Walter Clark Hovey, Nokomis, Ill Medical Department of Washington University, St Louis, 1897, aged 57, died, March 1

Charles O Linder, Spokane, Wash, Thomsonian Medical College, Allentown, Pa, 1905, aged 62, died, February 18

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

VITAMIN C VALUE OF LEMON AND OF LIME JUICE

To the Editor.—In reply to an inquiry as to the relative value in vitamin C of the lemon (*Citrus limonum*) and the lime (*Citrus medica*) in *Queries and Minor Notes* (THE JOURNAL January 24 p 291) you stated that according to Ragnar Berg (Die Vitamine Leipzig S Hirzel 1927 p 402) orange juice is richer than lime and this than lemon. If the general proposition advanced that the vitamin C content of fruits increases with sweetness is correct then the sweet lime and sweet lemon ought to be the richer ones in vitamin. During the World War I read a statement in the *Lancet* that fresh lime juice is far inferior to fresh lemon juice as an antiscorbutic also that historical inquiry had shown that lime juice reputed to be so valuable in arctic expeditions was really lemon juice. There seems to be a contradiction of claims.

M D Connecticut

ANSWER.—The corrective statement to which our correspondent has reference was published in a paper by Harriet Chick, L Margaret Hume Ruth F Skelton and Alice H Smith The Antiscorbutic Principle in Limes and Lemons (*Lancet* 2 735 [Nov 30] 1918). These investigators were attached to the Lister Institute of Preventive Medicine in London. In his treatise on Scurvy Past and Present (Philadelphia, J B Lippincott Company, 1920) Alfred F Hess referred to this historical inquiry as follows:

This sketch is of exceptional interest because it treats of the oldest and most cherished antiscorbutic and particularly because it has unearthed a peculiar fallacy in their connection. As they state there would appear to be every reason for believing that the use of so-called lime juice was responsible for the disappearance of scurvy from the British navy in the first decade of the nineteenth century. It would seem however that the lime juice which gained this great reputation in the navy some 125 years ago was in reality lemon juice and that it was not until about 50 years ago that lime juice was really used. These authors show—by one of those striking human experiments which occasionally is available—that in a polar exploration which was organized in 1850 lemon juice was issued to each man and that no case of scurvy developed whereas in a similar expedition which went out in 1875 lime juice was used and scurvy developed the following spring with great severity among the sledge crews. This investigation therefore seems to prove that lime juice the prototype of antiscorbutics has been recorded a false position that in reality the sailors of the past have been protected by lemon juice (p 149).

A history of the subject involving the use of lime juice and other antiscorbutic foods was published by Alice Henderson Smith A Historical Inquiry into the Efficacy of Lime Juice for the Prevention and Cure of Scurvy (*J Roy Med Corps*, February and March 1919). Some of the features of controversy are discussed by E V McCollum and Nina Simmonds The Newer Knowledge of Nutrition (New York, Macmillan Company). They point out that adulteration of lime juice has undoubtedly taken place in the past and that heretofore may have destroyed antiscorbutic potencies. In his recent book Professor Henry C Sherman of Columbia University has made comparison of the fresh juices of the orange, lemon and lime in the ratio of 100 100 25 (Sherman H C Food Products New York Macmillan Company 1924 p 414, Chemistry of Food and Nutrition, 1926 p 429). Thus the consensus of expert opinion is clearly against that of the German writer whose statement was accepted without further investigation.

REGENERATION OF PANCREATIC ISLANDS OF LANGERHANS

To the Editor.—In the December isue of *Hygiene* Dr B C H Harvey said on page 1138 in his article on human anatomy that in experimental animals ways have been found to make new islands grow. They are not so nearly perfected as to make them applicable to human beings but they are being tried out. Dr Harvey refers to the islands in the pancreas which create insulin. Will you kindly advise the name and location of the institution where the experiments are being made?

CARL G WILLIGS, Dallas, Tex

ANSWER.—Some of this work has been done in the University of Chicago in the department of anatomy. Accounts of it can be found in:

Grauer T P Regeneration in the Pancreas of the Rabbit *Am J Anatomy* November 1926
De Takat Geza Hannett Frances Hentley Dorothy and Sier I J Correlations of Internal and External Pancreatic Secretion *Arch Surg* 20 866 (May) 1930
Shields Warren Pathology of Diabetes Philadelphia 1930
Bensley Lectures of the Harvey Society New York February 1935

DISINFECTANTS

To the Editor — As head of the Wellington schools I am attempting to locate a satisfactory disinfectant. I find that the phenol coefficient values as given on commercial disinfectants do not give the information that is required for their intelligent use. Coefficients given, if not very carefully checked, are high on disease germs that are not prevalent in schools.

Would you kindly recommend to me the types of disinfectants most satisfactory for schools? We have had some experience with pine oil and have had highly recommended to us chlorine disinfectants.

What we wish is a disinfectant to be used for general school purposes. In other words we would like a disinfectant that we may spray in our halls, class rooms and lavatories that will kill disease germs that are prevalent among school children. We have epidemics of mumps, measles, chickenpox, scarlet fever, diphtheria, colds, influenza and numerous other childhood diseases. What we would like is something that would be of actual help in destroying these germs. We would be glad to know of solutions that we can put in our scrub water to use in our lavatories, urinals and toilet bowls. Likewise for the mopping of our toilet floors, shower baths and dressing rooms. We would be glad to have recommended something else if necessary to spray our class rooms and corridors with. I trust that this letter puts before you our problem. We are glad to spend money to cut diseases among our pupils. We feel however it is a waste of money to buy some disinfectants and use them for all types of school fumigation. If I have not yet been specific enough, won't you please pass direct questions so that I may answer them. This is truly a problem for school men and your association is certainly the one who, of all associations, should be able to help us.

A. M. McC

ANSWER — In combating contagion modern sanitary practices have eliminated disinfectants for spraying walls, ceiling and floors of school rooms. The source of infection is the individual, so long as the infected individual is present in the room, any disinfectant that might be used on the walls or the floor would be of little if any value in preventing infection. Removal of the infected individual usually suffices to end the danger of spreading the infection.

Soap and water is the best agent for cleaning floors, together with plenty of fresh air and sunshine. It is unnecessary to worry about contagious disease organisms that may be lodged on the walls or ceilings, the same rule applies to toilets and urinals. Cleanliness will take care of the whole problem without resort to strong disinfectants. In fact, terminal disinfection, such as fumigation with formaldehyde, has been generally discarded as valueless. In the case of lavatories, urinals and toilet bowls, so-called germicides in reality accomplish nothing except covering up the primary odor by the stronger odor of the chemical used.

"Disinfection of hands" may be obtained by a thorough scrubbing with soap and water. In laboratories in which pathologic material is being handled, a solution of mercuric chloride or a solution containing "compound solution of cresol" may be employed.

USE OF ANTITYPHOID VACCINATION FOR MEDICAL ATTENDANTS

To the Editor — To date I have held to earlier training that typhoid vaccine was not used for contacts and any one nurse or physician, caring for cases should not receive it during their attendance on cases. Is it now recognized therapy and if so on whose authority?

B. A. WINNE, M.D. Johnstown, N. Y.

ANSWER — Obviously, all reasonable efforts should be made to prevent typhoid infection in persons who are in special danger of such infection, and the injection of typhoid vaccine is the only reliable and effective means of prevention at hand. Whether the vaccine should be given during the attendance of a nurse or physician on cases of typhoid will have to be decided in each individual case. The only objection to giving the vaccine at such time would be the possibility that the recipient might be more or less ill in consequence, but such illness would be only temporary.

RELATION OF EYESTRAIN TO CATARACT

To the Editor — Will you kindly inform me whether eyestrain of an astigmatic condition, presbyopia, unequal in the two eyes and imbalance of ocular muscles resulting in moderate diplopia and with some cyclophoria might or in any probability would if uncorrected by glasses worn continuously for distant vision be apt to cause or hasten cataract in a person aged 52. Is there any real scientific evidence to support this idea or reasonable probability of it? Please omit name and address.

M.D. California

ANSWER — There is not one iota of scientific evidence that eyestrain, so called, due to uncorrected errors of refraction or imbalance of ocular muscles will cause or hasten the maturity of cataract of any sort in any individual of any age. It was a common belief among the older American school of refractionists that accurate correction of errors of refraction retarded the maturity of incipient cataract, but the belief was not founded on scientific evidence.

New Jersey October Examination

Dr. James J. McGuire, secretary of the Board of Medical Examiners of New Jersey, reports the written examination held at Trenton, Oct. 21-22, 1930. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Nineteen candidates were examined, 18 of whom passed and 1 failed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1929)	80.2	
George Washington University Medical School	(1929)	85.8	
Tulane University of Louisiana School of Medicine	(1929)	86.3	
Boston University Medical School	(1926) 80.5	83.5

Book Notices

CLINICAL ALLERGY PARTICULARLY ASTHMA AND HAY FEVER MECHANISM AND TREATMENT By Francis M Rackemann M.D. Physician to the Massachusetts General Hospital Boston. Cloth. Price \$10.50. Pp 617 with 30 illustrations. New York: Macmillan Company 1931.

Allergy as a specialty in scientific medicine is comparatively new. Our knowledge of the subject is almost wholly a matter of the twentieth century. The rapid increase in this knowledge makes almost any textbook obsolete with the date of publication. Actually, however, but few textbooks have thus far been available, notably, the books by Brown, Balyeat and Duke. It is doubtful whether any of these has endeavored to handle the subject with the completeness from the point of view of medicine as a whole that is revealed in Rackemann's contribution. The book bears an excellent introduction by Hans Zimsser and the series of which it is a part has had the editorial supervision of Minot.

The point of view toward allergy has gradually changed from emphasis on an immunologic background to a biochemical conception. It seems possible that the early emphasis on immunology did more to confuse the matter in the mind of the practitioner than it did to aid him. Dr Rackemann's contribution is planned primarily for the clinician. True, it offers an historical survey of the subject and a theoretical background, but it steps promptly into practical considerations of the chemistry of hypersensitivity, to immunology, and the possibility of desensitization. Dr Rackemann considers the various theories as to the nature and origin of allergy. He emphasizes the fact that normal man is sensitized with difficulty but that allergic individuals become sensitized with greater ease.

It is not yet understood just why some people become allergic at certain ages, but undoubtedly injections may offer opportunity for sensitization, heredity may play some part through the establishment of defects in constitution, and the nature of the response may be associated with the nature of the primary cause. Thus one person develops asthma, another hay-fever, a third urticaria, although all are sensitive to essentially the same proteins.

Dr Rackemann has collected carefully the entire literature on the subject, has organized it and has systematized it in such a way that the development of the knowledge is clear. In chapter IX he emphasizes the five definite characteristics of allergic individuals.

1 The presenting symptom whether asthma hay fever urticaria eczema angioneurotic edema migraine and perhaps other disorders is characteristic of the group.

2 Evidence of some other allergic symptom in the past or present history is usually at hand.

3 An inheritance of allergy can be identified in about one half the cases.

4 Positive skin tests are frequently elicited.

5 A blood eosinophilia when found is confirmatory (provided other causes of eosinophilia are excluded).

From this point on the book becomes wholly practical and therefore of special value to the practicing physician. The diagnosis, the clinical manifestations and the treatment of

allergic conditions are fully set forth. Numerous examples and case reports enliven the text. The book is exceedingly readable. It is printed in good type and concludes with a discussion and summary, an appendix which provides an alphabetical list of proteins, besides pollens, which may produce allergic manifestations, and a collection of nostrums for asthma with their content. An excellent index completes the book. A monograph of this type represents the most valuable of modern contributions to medical literature. Here is made available present knowledge of a highly technical subject in understandable form, properly systematized and useful.

HANDBUCH DER MIKROSKOPISCHEN ANATOMIE DES MENSCHEN Herausgegeben von Wilhelm v. Mollendorff. Band VI. Blutgefäss und Lymphgefässapparat. Atmungsapparat und innersekretorische Drüsen. Teil I. Blutgefässe und Herz. Lymphgefässe und lymphatische Organe. Milz. Bearbeitet von A. Benninghoff, A. Hartmann und T. Hellman. Paper. Price 148 marks. Pp 554 with 299 illustrations. Berlin: Julius Springer 1930.

This volume includes topics that enter into almost every histologic study and covers fields in which great progress has been made in recent years. The chapter on the blood vessels and heart is by Benninghoff; that on the lymphatic vessels and tissues by Hellman; and that on the spleen by Hartmann. All three authors are active workers in their respective fields, have a physiologic point of view and present a mass of well organized material including numerous new observations particularly on human material. The detailed and critical reviews of the literature are exhaustive at least so far as the German literature is concerned. The evaluation of the cytologic criteria of differentiating types of cells is occasionally open to question but in most such cases further experimental work will be necessary to establish cell relationships. The great variability in the structure and functions of the spleen in different vertebrates has been a source of confusion in the past and all experimental workers will welcome the presentation of the comparative histology which is based on a wide first hand knowledge.

DEEP X-RAY THERAPY IN MALIGNANT DISEASE. A Report of an Investigation Carried out from 1924-1929 under the Direction of the St. Bartholomew's Hospital Cancer Research Committee. By Walter M. Levitt, M.B., D.M.R.L. Medical Officer in Charge of the Radiotherapeutic Research Department. With an introduction by Sir Thomas Horler, K.C.V.O., M.D., F.R.C.P., Chairman of the Cancer Research Committee. Cloth. Pp 128 with 10 illustrations. London: John Murray 1930.

Although prepared by Dr Levitt, medical officer in charge of the radiotherapeutic research department of St. Bartholomew's Hospital, this report of the results of high voltage roentgen therapy in malignant disease during the past five years has the endorsement of the Cancer Research Committee, the members of which cooperated in the selection and subsequent observation of cases. The investigation was restricted to four groups corresponding to the four groups of cases in which research on radium treatment was being carried out: (1) malignant disease of the breast; (2) malignant disease of the uterus (cervix, vagina and vulva); (3) malignant disease in the upper air passages (mouth, nose, larynx, pharynx and accessory sinuses); (4) malignant disease of the esophagus. Two other groups were added in 1925 and 1928 respectively: (5) malignant disease of the rectum; and (6) malignant disease of the thyroid gland. As far as possible, the cases were selected and followed up by the same observer, one or two members of the committee being delegated to have charge of each group of cases. The total number of cases included in the investigation was 327; in only a small proportion of which the patient failed to return, the follow up examinations were made at intervals of three weeks for six months after treatment if the patients did not live at a great distance, or at intervals of one or two months when they lived at too great a distance. In the latter examination at more frequent intervals by the local physician was required. For various reasons a biopsy was omitted in thirty cases. A complete blood count was carried out before and from time to time during and after treatment. Roentgenographic examination of the lungs and mediastinum was carried out in all cases of carcinoma of the breast, all cases of disease of the upper air passages presenting enlarged subglottic glands, all cases of carcinoma of the esophagus, and all cases of sarcoma. In most of the patients the disease was relatively advanced but, with a few exceptions obviously more

bund or markedly cachectic patients were excluded. In all cases except those of sarcoma the object of the treatment was to secure a quantity of radiation of not less than 100 per cent and not more than 120 per cent of the erythema dose uniformly distributed throughout the region involved in the disease and the associated glandular areas.

In the great majority of cases a remarkable improvement in the general condition of the patient followed the treatment, even when the size of the growth did not diminish. In the fifty cases included in the breast group the disease usually was advanced and inoperable, the more favorable cases being treated with radium. This must be taken into account in evaluating the results. Of the ten cases treated by the single massive dose method, improvement was noted in only two, and the growth did not disappear in any case. Of the twenty-eight cases treated by the split, or fractional dose method the growth disappeared completely in eight cases. The forty-eight cases in the uterus group included some that were operable. Some were treated with roentgen rays exclusively and others with roentgen rays and radium. In some of the latter the roentgen treatment preceded the radium treatment, whereas in others the radium was used first. Of the sixteen cases of carcinoma of the cervix treated by roentgen rays only the disease disappeared completely in six cases, as well as in six other cases in which the intended radium treatment had not yet been applied. In eight cases in which the tumor disappeared after roentgen treatment alone, recurrence appeared later but improvement in these cases was again observed after radium treatment. In four of the six cases of carcinoma of the body of the uterus treated by roentgen rays exclusively all evidence of disease disappeared and two patients were still well after four years. Among the 170 cases of malignant disease of the upper or passages four of seven carcinomas and two endotheliomas of the palate were apparently cured. An apparent cure was obtained also in three of seven cases of sarcoma of the pharynx. In carcinoma of the tonsil, the results were uniformly bad. Complete disappearance of the malignant growth also was obtained in three of eleven cases of postcricoid carcinoma. Of the 132 cases treated with roentgen rays alone, all signs of disease disappeared in 15 per cent. Of the thirty-eight cases treated with roentgen rays and radium, all evidence of disease disappeared in 17 per cent. In the rectal and esophageal cases the results were not promising. Of the 319 cases of all groups, 15 per cent were free from evidence of disease at the time of the report, about 56 per cent derived substantial benefit and in 29 per cent the malignant process was not appreciably influenced.

This summary gives but a faint idea of the many points covered by the report. The technique employed, the reasons that led to the selection of technique, the methods of combining roentgen rays and radium, and the relative value of the single and fractional dose methods are clearly described and sanely discussed. The numerous statistical tables are admirably arranged. This may be regarded as a model of what such a report should be and will be invaluable to radiologists, surgeons and practitioners. Dr. Levitt deserves much credit for its preparation.

CLINICAL AND EPIDEMIOLOGICAL OBSERVATIONS ON TROPICAL TYPHUS IN THE FEDERATED MALAY STATES. By Raymond Leithwaite. *Bulletins from the Institute for Medical Research, Federated Malay States No. 1 of 1930.* Paper. Pp. 42. Kuala Lumpur: Malay States Government Printing Office, 1930.

EXPERIMENTAL TROPICAL TYPHUS IN LABORATORY ANIMALS. By Raymond Leithwaite. *Bulletins from the Institute for Medical Research, Federated Malay States No. 3 of 1930.* Paper. Pp. 10. Kuala Lumpur: Federated Malay States Government Printing Office, 1930.

This is a study of 164 cases of tropical typhus (so called by Fletcher and Lesslar, *Bull. Inst. M. Research*, Kuala Lumpur, F. M. S., 1925, number 2) occurring in the Federated Malay States from January 1927, to April, 1929. Of this series 154 were of the K type (rural) and 10 of the W type (urban). Clinically the two types are identical and resemble exanthematic typhus. The clinical and serologic manifestations are given which make possible a differentiation from tsutsugamushi disease, leptospirosis and typhoid. The serum of the urban type agglutinates indologenic strains of *Proteus* X 19 but not the anindologenic strains. Serum of the rural type agglutinates the anindologenic but not the indologenic strains of *Proteus* X 19. Epidemiologically, the W cases occur mainly among indoor

workers, whereas the K cases occur among those working or living in the countryside. The disease is nonseasonal and non-louse borne but has a clear occupational distribution. The W form occurs in those with diverse indoor occupations. The K form occurs in workers on plantations, in cowherds or bullock cart drivers, and in pruners of oil palms. Various conjectures are made relative to the possible vectors of the disease. It would seem that the epidemiology of transmission most resembles that of tsutsugamushi.

Inoculations of blood from patients suffering from tropical typhus were made to guinea pigs, rats and rabbits. Only five of the sixty-two guinea-pigs showed febrile reactions. The features of these reactions correspond with those in experimental exanthematic typhus but do not present so definite a course as the latter. Blood from sixty-two patients between the fourth and the eighth days of fever was inoculated into eighty-seven rats (*Rattus rattus-diardi*). There was a rise in temperature in twenty-three of these rats. Inoculations of emulsions of brain, spleen and kidney of those rats showing the most definite febrile reactions were made to other rats and to guinea pigs. Of 148 rats thus inoculated, 37 gave febrile reactions. It is concluded that the virus of tropical typhus is transmissible to rats, but with inconstant successful infections. Two of eleven rabbits inoculated with patient's blood gave positive Weil-Felix reactions.

LAUSCULTATION DANS LE DIAGNOSTIC DE LA TUBERCULOSE PLEURO-PULMONAIRE. Par René Burnand. Préface du Professeur F. Bezançon. Paper. Price, 40 francs. Pp. 195 with 51 illustrations. Paris: Masson & Cie, 1930.

This careful work on physical diagnosis carries a preface by Professor Bezançon who voices a protest, which seems to be as necessary in France as it is in America, against the tendency of many medical men to place a high value on roentgen diagnosis to the exclusion—or limitation—of careful stethoscopy. Burnand considers that the medical profession has forgotten the finer distinctions of physical sign description developed by our elders in the art. He admits that perhaps briefer and broader formulas have been gained but thinks that while these attain a greater simplicity they fail in large measure to mirror correctly the realities. It is necessary, therefore, to revive and reform our stethoscopy as well as to restate our conceptions. Nevertheless, Burnand would in no degree deprecate the use of the x-ray film. Laboratory methods are of inestimable value but should not be accorded full superiority in diagnosis. The author has gone deeply into his subject and has brought the text in excellent contact with the illustrations. Much attention is given to the various aspects of pulmonary tuberculosis and its complications. The book is noteworthy among the many recent publications on the subject of physical diagnosis.

MICROBIOLOGY AND ELEMENTARY PATHOLOGY FOR THE USE OF NURSES. By Charles G. Sinclair, B.S., M.D., Major, Medical Corps, U. S. Army. Cloth. Price \$2.50. Pp. 362 with 102 illustrations. Philadelphia: F. A. Davis Company, 1931.

The book deals with general microbiology, 228 pages, laboratory exercises in microbiology, 20 pages, and elements of pathology, 106 pages. The presentation is clear and simple. The information impresses one as well selected and it is reliable. The length of the different parts is well adjusted to the time available in the standard courses for nurses. The book, which is the outcome of the author's experience in teaching nurses, will be a valuable help to student nurses and a good guide for instructors of nurses in microbiology and pathology.

A CHART TO ILLUSTRATE THE HISTORY OF BIOCHEMISTRY AND PHYSIOLOGY. By Joseph Needham. Paper. Price, 10/6. Two charts. Cambridge: The Author [n.d.].

This chart represents a quick reference history not only of physiology and biochemistry but also of anatomy, chemistry, science and philosophy. There is a brief description of earlier medicobiologic science, and individual references to prominent investigators who lived between 1400 and 1900. For each man one finds easily the years of his birth and death, the place where he worked, the nature of his contributions to his particular branch of biology and the names of his teachers and pupils. The chart may be recommended to every one interested in the history of biology and medicine and should be hanging on the wall in every physiologic and biochemical teaching or research laboratory.

Medicolegal

Sarcoma of a Bone Attributed to Trauma

(Halper *The Golden Rule (Minn.)* 231 N W 195)

Minnie Halper, a clerk in the Golden Rule Department Store, Oct 23, 1928, was carrying a box weighing 44 pounds. It fell and struck her on the inner side of her leg, "just below the point of the knee." The blow left a red mark, which turned blue and black. Her leg pained her for a few days, and then apparently it seemed normal. A few weeks later the leg pained her again and began to swell at the place of the injury. December 29, she complained of the pain, to the nurse in the hospital or rest room at her place of employment whom she had occasion to consult about another ailment. She did not associate it, however, at that time, with the injury she had suffered, nor did she do so until after the physician whom she first consulted, February 2, questioned her. Roentgenograms taken after that consultation showed that the bone was affected. An incision was made, February 10, and material was removed for microscopic examination. One pathologist thought that the examination disclosed a sarcoma, the other thought that it did not. Another examination, March 13, resulted in a definite diagnosis of sarcoma. The leg was amputated, April 17, three inches above the knee. The industrial commission awarded compensation for the loss of the leg. The employer and its insurance carrier brought the case by writ of certiorari to the Supreme Court of Minnesota.

The medical witnesses agreed, said the Supreme Court, that no one knows positively what causes sarcoma or whether it may result from trauma. One physician testified that in a majority of sarcoma cases there had been a previous, comparatively trivial injury, the effects of which passed away, only to be followed by a sarcoma. Another testified that a large percentage of patients having sarcomas give histories of previous trauma. Both believed that the sarcoma in the present case resulted from the injury. The sarcoma developed in the exact point of the injury, and there was nothing to indicate any other cause. In the opinion of the Supreme Court, the evidence justified the industrial commission in inferring that the sarcoma resulted from the injury. The order of the commission was therefore affirmed.

Practice of Medicine by a Barber, Entrapment

(Piper v State (Wis.) 231 N W 162)

An inspector for the board of medical examiners called at Piper's barber shop. He was invited into a rear room, having a sign "Office" on its door. The inspector told Piper that he understood that he, Piper, was "handling venereal diseases" and that he desired treatment. Piper asked several questions as to his supposed patient's symptoms. He then made a diagnosis of "prostate gland trouble" and said that if the disease was not handled correctly a cancer might develop. Piper's remedy was to rub a liquid preparation of his own on the back and permit the resulting blisters to remain on seven days, using pork lard and ordinary cotton batting when the pain became too severe. This treatment, he stated, would produce a sort of localized smallpox, which would drive the poison germs out of the system and keep the disease from spreading. Piper then sold to the inspector a bottle of medicine for which he charged five dollars. He was convicted of practicing medicine without a license and appealed to the Supreme Court of Wisconsin.

One of the grounds on which Piper based his appeal was that the inspector had entrapped him and that the deceit used rendered inadmissible the inspector's testimony. Merely setting a trap to catch a would-be criminal said the Supreme Court, by affording him the freest opportunity to commit an offense does not sacrifice any element of the offense. *Topolucki v State* 130 Wis 244, 109 N W 1037 7 L R A (N S) 756 118 Am St Rep 1019, 10 Ann Cas 627. The fact that a party against whom a crime is contemplated suggests and encourages or sets a trap for the accused, is not a defense where the accused has done every act essential to the completion of the offense. *Kosack v State*

160 Wis 255, 152 N W 181. In the present case, continued the court, the inspector did nothing to relieve Piper from any element of the offense. The conduct of Piper, not the motive or the deception of the inspector, must be considered. The judgment of the lower court was affirmed.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Suppurations Within Chest A M Shipley Baltimore—p 1
*Treatment of Abortions G Metzler Bridgeville—p 6

Treatment of Abortions—Metzler believes that the present-day treatment in febrile cases of abortion seems to be tending toward the conservative methods. In absence of severe hemorrhage the expectant treatment is continued until the temperature has remained normal for five or six days. While this procedure seems to produce the best results in the majority of febrile cases there are instances in which emptying of the uterus markedly shortens the febrile state. In septic cases in which the cervix is open and there is a foul mass of necrotic tissue retained in the uterus, removal with as little instrumentation as possible followed with iodoform packing seems to lead to rapid recovery. Cases of general septicemia appear to yield only to the expectant form of treatment which is the one

used almost entirely. The tendency seems to be toward placing more importance on the prophylactic treatment of abortions than was formerly done and toward conservative methods of treatment in the majority of cases, yet varying from these in certain isolated cases.

Changes in Course of Dementia Paralytica Under Malarial Therapy L W Yule Wooster—p 139
*Health Hazards in Chromium Plating J Blair Cleveland—p 142

Ulcerative Colitis—According to Arn, the majority of patients with chronic ulcerative colitis will respond favorably to medical treatment. Surgical intervention should not be contemplated until medical treatment has been given a thorough trial. In five cases of advanced chronic ulcerative colitis, which were refractory to the usual forms of medical treatment, clinical cures were obtained by ileosigmoidostomy, followed by daily colonic irrigations.

Health Hazards in Chromium Plating—Blair states that there is no evidence, from the literature or otherwise, that any injury arising from contact with chromic acid solution or spray in chromium plating develops into a constitutional disease. The ulceration and perforation of the nasal septum as well as the formation of chrome sores on other parts of the body are only local in their action; they are not in themselves of grave consequence and do not lead to permanent disability and are seldom severe enough to necessitate absence from work. With the recognition of the hazard, prevention and treatment should be easy.

Lancet, London

1 171 224 (Jan 24) 1931

- *Technic and Results of Myomectomy V Bonney—p 171
*Etiology of Peptic Ulcer L O Shughnessy—p 177
*Irradiation of School Children L Hill and A R Laurie—p 182
Melanoma Following Crab Yaws C C Chesterman—p 183

Technic and Results of Myomectomy—Bonney states that, although cases of fibroids beyond the scope of conservative surgery are uncommon, this must not be interpreted to mean that myomectomy is the operation of choice in the majority of patients suffering from these tumors. Myomectomy varies immensely in magnitude in different cases, being sometimes much easier than the corresponding hysterectomy, and sometimes much more difficult. For women over 41 years of age it is to be preferred to hysterectomy only when it is obviously the lesser operation of the two, or when the patient for reasons of her own wishes it. For women of 41 and under it should, broadly speaking, be the operation of choice, but there are exceptions. The patient may desire the removal of the uterus either to free herself from the possibility of conception or to escape the monthly annoyance or pain of the periods or she may present such extreme anemia as to render continuance of the menses undesirable. Myomectomy should not be performed unless the uterus, apart from its contained fibroids, is reasonably healthy, nor ever unless the surgeon feels sure that the fibroids themselves present no suspicion of being malignant. The various forms of nonmalignant degeneration—"red" myomatoid, hyaline, cystic, nevoid—do not in the least contraindicate conservatism, and this is especially noteworthy of "red" degeneration, with which pyrexia is so often associated. The author has with impunity enucleated such fibroids on many occasions.

Etiology of Peptic Ulcer—O'Shaughnessy describes experiments on cats which show that it was possible to produce the various stages of acute ulcer by injections of histamine into the muscular layer of the stomach wall. One ulcer having the appearance of a chronic ulcer was noted. Histamine is a product of protein disintegration and is produced by dead bacteria as well as by dead tissue, it seems to be a factor common to all the multitudinous methods that have been employed to produce ulcer experimentally and to the various processes that have been supposed to produce it clinically, it is a factor that links the simple injection of serum used by Bolton with the grossly mutilating surgical experiments of Mann, it is present in the cultures of streptococci employed by Rosenow, it is absorbed from the burnt surface of the skin, it is present in the various septic foci whose removal occupies so prominent a place in the present day therapy of the disease.

Irradiation of School Children—Hill and Laurie present the results of a controlled investigation of the effects of irradiation of school children. Four areas of the town of Derby were selected—roughly North, South, East and West—and a random sample of 100 children were taken from each area. Four groups were formed, each group consisting of twenty-five children from each area, so that all groups were comparable as regards living conditions. The ages were between 9 and 12 years, and, as the groups were formed by random sampling, any effect of age was minimized. The test extended over sixteen weeks. The children in group 1 were given radiation 6 feet away from a long flame tungsten cored carbon arc twice weekly. The lamp ran on 85 volts and 15 amperes and the maximum dose was ten minutes back and ten minutes front 6 feet away and this given twice a week. The children in group 2 were given one viosterol pellet at school daily. Each pellet has a dosage of vitamin D equivalent to that in about 2 ounces of cod liver oil. The children in group 3 were given exactly similar looking pellets but containing no viosterol daily and attended, also for exposure to an arc fitted with a glass screen twice a week. This group was put in to demonstrate the part if any, that psychology plays in the taking of pellets and the mere fact of undressing before a lamp. The children in group 4 were controls, who had nothing done for them at

all. It was noted that 1. Marked improvements under any particular heading or class of headings, were always shown in groups 1 and 2, and not by a small margin that could be due to fortuitous circumstances, but by a really appreciable margin. 2. In no case did groups 3 and 4 show better results than 1 and 2. 3. Group 1 always showed slightly better results than group 2. 4. In no case, in groups 1 and 2, was there any retrogression in the health of the children, except in the single instance of enlarged cervical lymph nodes, for which there was an underlying cause, untreated except by irradiation. 5. The cases that showed really spectacular improvements were in group 1.

Diagnosis and Serum Treatment of Poliomyelitis—Helms reports that there have been few cases of poliomyelitis in Sydney during the last nine months. Five patients, all of whom already had paralysis, have been given convalescent serum. In two of these there was no further paralysis, and the rate of recovery has been satisfactory. The serum may or may not have had a beneficial effect in these instances. A third patient had bulbar paralysis at the time of administration. Paralysis spread to the intercostal muscles and the child died thirty-six hours later. A fourth patient had extensive paralysis of the four limbs and trunk. He died two weeks later from pneumonia. The case is interesting in view of the fact that there was no increase in the cell content of the cerebrospinal fluid thirty-six hours after the appearance of paralysis showing that meningitis was at a minimum, although there must have been considerable involvement of the anterior horn cells.

Roentgen Examination of Blood Vessels by Injecting Iodized Poppy-Seed Oil—Saito et al. describe a method of arteriography and venography that consists of injecting, into the vessels an extremely fine emulsion of iodized poppy seed oil or of iodized sesame oil. They have used this method successfully in numerous cases. They give in detail the composition of the different emulsions that they have tried. The injection is made with a large needle and as rapidly as possible so that the emulsion is not diluted by the blood in the vessels. In case of arteriosclerosis puncture of the principal arteries is not possible and the emulsion is injected into one of the branches of the arteries. To make a venography the portion of the body to

be examined is ligated with two bands of caoutchouc and the emulsion is injected into a vein between the two ligatures. These injections do not cause dangerous reactions such as are produced by sodium bromide or sodium iodide because the emulsified oil is absorbed into the tissues in the same way as the oil or fats contained in chyle when it enters the blood vessels. The iodine is eliminated gradually in the urine. The injections themselves are not painful, although the patient may notice a slightly abnormal sensation in the veins and arteries. As a result of the harmlessness of the method and of its extreme efficacy, the authors have been able to secure arteriographs of the brain during life, local roentgen examination of cerebral tumors, diagnosis of arterial thrombosis in patients with gangrene, examination of the modifications of the blood vessels after amputation of limbs, examination of varicose veins and so on.

*Constitution and Heredity in Pathogenesis of Gastroduodenal Ulcer
E. Jacarelli—p. 1809

Constitution and Heredity in Pathogenesis of Gastroduodenal Ulcer—Jacarelli, after recalling the recent researches on the importance of constitution and heredity in the pathogenesis of gastroduodenal ulcer, reports his own observations on a family of thirteen members, ten of whom presented unquestionable signs of organic gastroduodenal lesions, almost all of an ulcerous type. The pathogenic importance of the constitutional and hereditary factors as demonstrated by statistical studies, is probably associated with the transmission of a special sensitiveness of the gastroduodenal mucosa resulting from congenital or acquired disturbances of the sympathetic nervous system, with frequent preponderance of the vagal section (vagotonia), on the mucosa thus predisposed may act secondarily various contingent factors, causing the formation of a round ulcer.

Mesenterium Ileocolicum Copmune Pathogenesis and Clinical Significance A. Zeitlin—p. 391

Intestinal Disturbances of Hypophyseal Origin—In a high percentage of the cases of adiposogenital dystrophy that he has observed, Strauss has noted various types of intestinal disturbances. Frequently there was a tendency to diarrhea, which in some cases was accompanied by pain and alternated with obstipation. The cecum was frequently distended, painful on pressure and of abnormal mobility. Similar changes were frequently present in the lower portion of the ascending colon. Roentgen examination was negative in many cases, but in some of them it revealed typhlitis with a low position and abnormal mobility of the cecum. Nearly all the cases occurred in middle-aged men with definite signs of adiposogenital dystrophy.

Disadvantages of Alkali Therapy in Diseases of Stomach—Mayer believes that in hyperacidic alkali therapy is of only problematic value. A complete neutralization of the excess hydrochloric acid is of extreme rarity. Moreover, in this condition the administration of alkalis is followed by an increased secretion of hydrochloric acid, thus the effect is the opposite of what is desired. The effect on the subjective disturbances is only transitory. The prolonged administration of alkalis in hyperchlorhydria, however, may lead to a disturbance in the functioning of the stomach which may terminate in true achylia gastrica. The use of alkali therapy as extensively as it has been practiced during the last few years in the clinic and in general practice is therefore unjustified. A more conservative attitude should be taken with regard to this form of treatment particularly in the use of large doses of alkalis.

Daily Blood Sugar Curve in Diabetes—Kroner states that occasionally in diabetes three determinations of the blood

sugar should be made in one day, namely, in the morning before the first meal, at noon shortly before the midday meal and in the evening before the last large meal. When the results of the determinations are plotted the curves are of significance with regard to the treatment. If the curve shows a midday drop in diabetic persons under insulin treatment it indicates that a sufficient amount of insulin is being given. If, on the other hand, the curve shows a midday peak it indicates that the amount of insulin being given should be increased.

Influence of High Frequency Current on Stomach—According to Kirstner and Lurje, in cases of normal gastric secretion and hypersecretion diathermic treatment causes a decrease in the secretory functioning of the stomach. In cases of hyposecretion it does not have an appreciable influence on the secretion. In all types of secretion the evacuation of the stomach is accelerated, the acceleration is particularly marked in cases in which the evacuation is slow before the diathermic treatment is given. Under the influence of diathermy, various gastric disturbances disappear rapidly. The influence of diathermy depends not only on the heat action but also on the specific action of the high frequency current (electrical effect). Of great importance with regard to the curative effect of diathermy in disturbances in the secretory and evacuant functioning of the stomach is the correct application of the electrodes.

Effect of Sodium Chloride-Free Diet on Tuberculosis—Herrmannsdorfer's article consists exclusively of six case histories of tuberculous persons and twenty one plates showing the condition of the patients before and after treatment by a sodium chloride free diet. The conditions treated were varied, namely, one instance of lupus vulgaris of the face and nasal mucosa, one of tuberculous caries of the right tenth eleventh and twelfth ribs with fistula and ulcer formation on the back, bilateral, cirrhotic proliferative pulmonary tuberculosis, cold abscess with fistulas on the left thigh, right forearm and right axilla, one of tuberculous peritonitis with inoculation tuberculosis in a laparotomy scar and exudative pleurisy, one of phlegmonous ulcerative tuberculosis of the soft parts of the fingers, bone tuberculosis of the left wrist and middle portion of the hand, and tuberculosis of the left axilla and subpectoral lymph nodes, one of pulmonary tuberculosis with cavern formation in the right upper lobe, pneumothorax, exudate and empyema necessitatis, and one of lupus ulcerosus of the bridge of the nose, tuberculosis of the rectum with rectovaginal fistula and periproctal tuberculosis. In all the patients except the last one the prolonged use of the sodium chloride-free diet was followed by the healing of the tuberculous processes, and even in the last patient there occurred temporary improvement in the general condition.

Tuberculosis of Bones in Relation to Tuberculosis of Lungs—Schaafhausen reports the results of his study to determine the applicability of Ranke's principle of isolated organ tuberculosis to tuberculosis of the bones and joints. He found that in 100 cases of bone and joint tuberculosis the principle applied 94 times. In 24 per cent of the cases there was only one bone process without any demonstrable lung disease. In 46 per cent of the cases there was merely a primary complex in the lungs. In 24 per cent of the cases there was an extensive healed pulmonary process. In only 6 per cent of the cases did the patients have manifestations of an active pulmonary process.
